The Metals Reserve Co. purchased bauxite in Arkansas throughout 1943 for delivery to the four stock-pile depots at Sweet Home, Ward Spur, Lignite, and Hurricane Creek. A special price schedule for these purchases was set up based upon the percentages of contained silica and alumina in the ore. The base price was $4 a long ton for bauxite containing 13 percent silica and 50 percent alumina, and a bonus-penalty system provided that (1) each percent of silica under 13 would add 20 cents to the purchase price per ton; (2) each percent of silica over 13 would deduct a penalty of 43 cents; (3) each percent of alumina under 50 would add 14 cents; and (4) each percent of alumina over 50 would deduct 14 cents a ton from the purchase price. Effective September 1, 1943, a new schedule was set up providing that all prices on the previous schedule be raised 15 cents a ton. A penalty of 43 cents a ton for each percent of ferrous iron over 6 percent was also imposed.

FOREIGN TRADE

Imports of bauxite in 1943 increased 75 percent from 1942, reaching a record total of 1,733,596 short tons, and exports (dried equivalent) increased 80 percent and totaled 592,300 short tons, also a new high mark. Of the 1943 imports, 1,342,042 tons came from Surinam, 375,213 tons from British Guiana, 16,135 tons from Brazil, 114 tons from France, 86 tons from Yugoslavia, 6 tons from Jamaica,[3] and less than 1 ton from Canada, according to the United States Department of Commerce. By customs districts importations were as follows: 1,416,036 tons to Mobile, 317,353 tons to New Orleans, 201 tons to Buffalo, 4 tons to St. Louis, 2 tons to Florida, and less than 1 ton to St. Lawrence.

Of the 1943 exports, 445,547 short tons were classified as bauxite and other aluminous ores and 21,701 tons as bauxite concentrates

---

[3] Actually, according to the recipient of the Jamaica ore, approximately 2,500 tons were imported in March 1943, but this is not shown on U. S. Department of Commerce records.

(including alumina). Canada was the largest recipient of the exports, 444,503 tons of bauxite and other aluminous ores being shipped to that country; only 518 tons went to Curaçao and the Netherlands West Indies, 408 tons to Cuba, and 118 tons to Trinidad and Tobago. Bauxite concentrates (including alumina) were exported to the following countries: Canada 21,418 tons, Trinidad and Tobago 283 tons, and Mexico and Australia less than 1 ton each.

Bauxite imported into and exported from the United States, 1939–43

Year	Imports for consumption [1, 2]		Exports (including bauxite concentrates) [3]		Year	Imports for consumption [1, 2]		Exports (including bauxite concentrates) [3]	
	Short tons	Value	Short tons	Value		Short tons	Value	Short tons	Value
1939	582, 600	$3, 765, 140	57, 831	$1, 117, 564	1942	990, 323	$5, 952, 451	291, 872	$5, 086, 695

[2] Chiefly dried ore.

[3] As shipped.

ALUMINUM

PRODUCTION

Primary.—The production of 920,179 short tons of primary aluminum in 1943—77 percent more than the 521,106 tons produced in 1942—represented another all-time high mark for the aluminum industry. Output in each of the past 5 years has broken all previous records, but the mark set in 1943 probably will stand for at least the duration of the war, owing to a cut-back in production announced early in 1944. The average annual rate of production reached during December 1943 was about 1,100,000 short tons of metal. As a result of the cut-back ordered by the War Production Board, the average annual rate of production dropped steadily and in May 1944 was only slightly more than 900,000 tons and about equivalent to the June 1943 rate. Estimates by the War Production Board indicate that the rate will drop to about 810,000 tons in June and remain there for the remainder of the year. Total estimated 1944 production is 867,600 short tons—about 6 percent less than 1943 output. United States production in 1943 slightly exceeded the estimated output of the entire world in 1940.

The five aluminum-reduction plants of the Aluminum Co. of America (Alcoa) and the eight Defense Plant Corporation plants operated by Alcoa produced by far the largest share of the 1943 output. Reynolds Metals Co. was the second-largest producer from its two plants at Listerhill, Ala., and Longview, Wash. Olin Corporation was the only other producer in the field, with a Government-owned plant at Tacoma, Wash. Approximately 54 percent of the output was from privately owned facilities and 46 percent from Government-owned plants. Of the Alcoa output from privately owned plants, 42 percent was made at Alcoa, Tenn.; 21 percent at Vancouver, Wash.; 19 percent at Massena, N. Y.; 13 percent at Badin, N. C.; and 5 percent at Niagara Falls, N. Y. Of the output at Alcoa-operated Defense Corporation plants, 22 percent was produced at Queens, N. Y.; 17 percent at Mead, Wash.; 16 percent at Jones Mills, Ark.; 13 percent at St. Lawrence (Massena), N. Y.; 12 percent at Troutdale, Oreg.; 10 percent at Los Angeles, Calif.; 6 percent at Burlington, N. J.; and 4 percent at Riverbank, Calif. The Listerhill (Ala.) plant of Reynolds Metals Co. supplied 61 percent of Reynolds production, and the Longview (Wash.) plant the remaining 39 percent. The value of the aluminum shipped in 1943 averaged 14.42 cents a pound compared with 14.62 cents in 1942.

During 1943 the expansion of all primary metal plants was completed. The Queens plant came into production in March, and the Burlington and Riverbank plants started operation during May. By November 1943 all reduction plants had reached virtual capacity except for three potlines—two at Los Angeles and one at Riverbank—which were not operated owing to a labor shortage. Shortly after the attainment of this objective, it became apparent that aluminum ingot was in a position of considerable oversupply. Current needs were more than being met, and on December 31, 1943, stocks of primary ingot at reduction plants, in excess of normal, and stocks of ingot stored in Canada for Metals Reserve Co. totaled nearly 140,000 tons and were growing at a rapid rate. Accordingly, at the instance of War Production Board, curtailments were brought into effect, and in the period from December 15, 1943, to May 31, 1944, cut-backs were made totaling 30 percent of installed capacity. By plants the cut-backs were as follows: Alcoa, Tenn., 10 percent; Badin, N. C., 13 percent; Massena, N. Y., 30 percent; Burlington, N. J., 67 percent; Los Angeles, Calif., 40 percent;[4] Queens, N. Y., 100 percent; Riverbank, Calif., 33 percent;[4] St. Lawrence, N. Y., 100 percent;[5] and Troutdale, Oreg., 25 percent.[6]

The Defense Plant Corporation alumina plant at Baton Rouge, La., began producing calcined alumina in March 1943, and construction work was completed in July. At Hurricane Creek (Bauxite), Ark., construction was essentially completed on the original plant by April 1, 1943, and the first expansion of 150,000 tons a year, begun in July 1942, was completed during August 1943. The second expansion at Bauxite, authorized in March 1943, calling for an additional 127,500 tons a year was completed early in 1944. In July 1943 a further over-all expansion of alumina capacity was proposed, totaling 300,000 tons to be distributed as follows: Hurricane Creek, 50,000 tons; Baton Rouge, 150,000 tons; and Listerhill, Ala., 100,000 tons. However, this proposal was quickly shelved, as it became increasingly apparent that alumina stocks were growing and that consumption at reduction plants would be cut. Reductions in output of alumina were effected early in 1944 by the War Production Board, and by about July 1, 1944, the cut-backs will be: Mobile, 30 percent; Baton Rouge, 100 percent; East St. Louis, 27 percent; and Hurricane Creek, 30 percent. These decreases in alumina production are expected to level off supply and consumption of this commodity.

Early in 1943 construction was begun on lime-soda-sinter units at the two Alcoa and the two Defense Plant Corporation alumina plants. These sinter units were for the purpose of treating the "red mud" resulting from Bayer treatment of high-silica bauxites to obtain much of the contained alumina not recoverable by the Bayer method. At the time the sinter units were proposed and construction initiated, it appeared that the United States might have to rely almost entirely on Arkansas bauxite for the production of alumina and that the alumina plants would have to produce at capacity to supply the growing aluminum output. Actually, during 1943 it became apparent that imports of bauxite were to be quite substantial, and near the end of the year it was obvious that the formerly planned rate of alumina production could be reduced considerably. Hence the sinter units, as accessories to the Bayer plants for the purpose of extracting the last possible pound of alumina from each ton of bauxite fed into the plants, became far less vital to the aluminum industry. Nevertheless, all four units are virtually completed, and all except that at Baton Rouge are in partial operation. During 1944 it is anticipated that only about 400,000 tons of South American bauxite will be imported, and thus a larger percentage of relatively high silica domestic ore will be used than in 1943. Whether the sinter units are operated continuously during 1944 probably will depend on the cost of the alumina recovered by them and the labor required per pound of output. At present it appears that they are not likely to operate at a substantial rate in the coming year unless some unexpected demand for alumina requires that the Bayer plants operate near capacity.

---

[4] Cut-backs actually represent potlines never put into production because of labor shortage.

[5] Instead of actually closing down all 3 lines at St. Lawrence, Alcoa is operating 2 of them under an agreement with Defense Plant Corporation and has curtailed an equivalent amount of production at Massena. Production of both public and private potlines is now considered as Alcoa-owned production.

[6] Curtailment here was involuntary, and potline was closed down because of a manpower shortage.

The Kalunite, Inc., alumina plant at Salt Lake City, Utah, did not produce any substantial quantities of commercial-grade alumina during 1943. As of June 1944 no predictions have been made as to when the plant will be in commercial operation. The proposed plant of Aluminum, Inc., at Marysvale, Utah, which was to have utilized a modified Moffat process in producing 18,000 tons of alumina a year from alunite, was definitely canceled in January 1944. In the fall of 1943 three small-scale semicommercial plants to produce alumina from clay and anorthosite were approved and construction was begun. The plant, to be operated by Ancor Corporation (American Nepheline Corporation), at Harleyville, S. C., will produce alumina from local clays and is expected to be in operation by early fall of 1944. Capacity will be 18,000 tons of alumina a year. At Salem, Oreg., the Chemical Construction Co. is building an 18,000-ton plant to produce alumina from clay. This plant is expected to be completed early in 1945. The third alumina plant, that of the Monolith Midwest Corporation at Laramie, Wyo., will process anorthosite and produce alumina at the rate of 18,000 tons a year starting some time in 1945.

In connection with the expansion of fabricating capacity of sheet, rod and bar, forgings, castings, and extrusions, numerous plants were constructed under the sponsorship of the Aluminum and Magnesium Division of the War Production Board during 1943 and early 1944, chiefly with Defense Plant Corporation funds. Most of these plants had been completed or at least were in partial operation by April 1, 1944.

Shortages in extrusion and rod and bar facilities which, early in 1943, constituted one of the chief bottlenecks in the expansion of aircraft production were alleviated during the latter part of the year by construction of new plants and by an easing in the labor situation. During the summer most fabricating plants experienced great difficulty with absenteeism and high quit rates and in obtaining sufficient labor. In general, the type of work was not attractive to workers because of heat in foundries and forges and because wage rates were not as high, or upgrading as rapid, as in the airplane and shipbuilding industries. An intensive recruitment drive for labor during the summer alleviated the difficulties somewhat, and by the end of 1943 and early 1944, when production cut-backs were announced, the labor problem ceased to be a major obstacle. Only in local areas, where the competitive demand for labor in shipbuilding and aircraft is high, does the situation present serious difficulties.

On April 28 the National War Labor Board awarded a wage increase of 4 cents an hour to 8,000 workers of the Bohn Aluminum & Brass Corporation. The labor dispute at the Alcoa Edgewater (N. J.) plant between employees of the remelt department and the company management was settled May 11 by an agreement giving the workers one double-time day every 6 weeks and assurance that transfers would be made as of Sundays and that additional employees would be placed on certain operations in the department. The National War Labor Board granted its first approval to an incentive pay scheme since the issuance of the "hold-the-line" order at the Lafayette (Ind.) extrusion plant of the Aluminum Co. of America on May 6. The Board's approval was subject to the provision that the plan should not increase the unit labor cost, and according to the company it will result in pay increases of about 20 percent for about 2,800 of the plant personnel of 5,000 and cause a production increase of 20 percent. A general wage increase of 4 cents an hour was granted on June 29 to 350 employees of the Fairmont Aluminum Co. at Fairmont, W. Va., under the Little Steel formula.

During early July a strike of 60 molders at the Bridgeport (Conn.) plant of Alcoa resulted in an almost complete stoppage of work. Less than a month later production was again halted by a walk-out in protest by the workers at having to purchase safety gloves for 63 cents a pair. In a move believed to be without precedent in the country, officials of the Aluminum Co. of America on July 23 commissioned employees of their Cleveland plant to reduce absenteeism and labor turn-over by their own methods. This plant has long been the focal point of much labor difficulty. On July 24 a 5-cent-an-hour wage increase was granted to all hourly employees of the Alcoa aluminum-reduction plant at Jones Mills, Ark., and of the Aluminum Ore Co. alumina plant at Hurricane Creek, Ark. Both increases were retroactive to April 1 and are based upon a similar increase granted to employees of the Republic Mining & Mfg. Co. at Bauxite, Ark., earlier in the year.

On October 19, 1943, the Supreme Court set aside for an indefinite period the Aluminum Co. of America antitrust case. The Court stated that since four justices have disqualified themselves from participating in the case it "will be transferred to a special docket and all further proceedings in it postponed until such time as there is a quorum of justices qualified to sit in it, when it will be restored to the regular docket for such further proceedings as may be appropriate." However, legislation signed by the President on June 10, 1944 (Public Law 332), provided that cases of this sort could be determined by the circuit court. The case has been sent by the Supreme Court to the Second Federal Circuit Court for final action.

Early in August a five-count indictment was returned against Bohn Aluminum & Brass Corporation and three of its officials charging them with fraud and sabotage. It was claimed in the indictment that conspiracy existed to repair and conceal defects in aluminum castings for Rolls-Royce airplane motors made by Packard Motor Car Co. The Bohn Corporation, in a formal statement, declared that the Government charges were based upon a "technical and impracticable interpretation of obsolete specifications." The company declared that "Peening and welding aluminum castings are no secret. Nor are they strange and uncommon procedures * * *."

"That we have followed a sound procedure is proved by the fact that there has never been a single engine failure due to an aluminum casting made by us." On May 12, 1944, Judge Frank A. Picard, of the Detroit Federal Court, dismissed the four charges of sabotage against the Bohn Corporation and three of its officials, leaving only a charge of conspiring to defraud the Government to be considered by the jury hearing the case.

Secondary.—Recovery of secondary aluminum in 1943 totaled 313,961 short tons compared with 196,464 tons (revised figure) in 1942 and 106,857 tons in 1941. The 313,961 tons recovered from secondary sources included 5,926 tons of pure metal (98.5+ percent), 305,357 tons of aluminum alloys, 1,279 tons of aluminum in brass and bronze, 219 tons in zinc-base alloys and 1,180 tons of aluminum in chemical products. Production in the form of secondary-aluminum ingot totaled 196,373 tons (144,694 in 1942). The secondary aluminum recovered in 1943 required the consumption of 352,124 tons of aluminum scrap, of which 34,266 tons or 10 percent was old scrap (43,248 tons or 20 percent in 1942) and 317,858 tons or 90 percent was new scrap (174,363 tons or 80 percent in 1942). Remelters, smelters, and refineries used 64 percent of this scrap; aluminum rolling mills, 35 percent; and foundries and other manufacturers, 1 percent. Additional information on secondary aluminum is given in the chapter on Secondary Metals—Nonferrous.

CONSUMPTION

Apparent domestic consumption of primary aluminum increased 49 percent over 1942. Consumption of secondary aluminum probably increased at an even greater rate.

Production, imports, exports, and apparent consumption of primary aluminum and production of secondary aluminum in the United States, 1939–43

Year	Primary aluminum					Secondary aluminum	
	Production		Imports (short tons)	Exports (short tons)	Apparent consumption [1] (short tons)	Short tons	Value [2]
	Short tons	Value					
1939	163,545	$64,600,000	9,290	36,632	167,646	53,947	$21,309,065
1940	206,280	75,292,000	17,435	26,886	227,017	80,362	29,332,130
1941	309,067	100,395,000	13,358	7,405	302,788	106,857	34,707,153
1942	521,106	151,371,000	112,112	38,747	[3] 588,969	[3] 196,464	[3] 57,446,074
1943	920,179	265,380,000	135,581	117,592	877,381	313,961	90,546,352

[1] Data not available on fluctuations in consumers' stocks. Withdrawals from producers' stocks totaled 31,443 short tons in 1939, and 30,188 in 1940; additions to producers' stocks totaled 12,232 tons in 1941, 5,502 in 1942, and 60,787 in 1943.

[2] Based upon average price of primary aluminum as reported to Bureau of Mines.

[3] Revised figures.

During the first half of 1943 a steadily growing share of total shipments went to aircraft plants, and in the latter half of the year shipments continued at approximately the same proportionate rate. About 68 percent of total shipments of fabricated products was consigned to aircraft plants for construction of airframes, landing gear, engines, propellers, and fittings. The bulk of the remainder was used in ship construction, tank engines, ordnance, and other military uses. Only a minimum of essential civilian needs, such as tools, chemical equipment, and other essential categories was filled. Pre-war uses of the metal, such as automobiles, trains, electrical conductors, furniture, household utensils, decorations, packaging, and bridge and building construction, have been virtually eliminated. However, there is some indication that during the latter half of 1944 some metal may be released for civilian manufactures in areas where both labor and facilities are available and there is a dearth of war contracts.

Consumption of aluminum in 1944 will follow a pattern similar to that in 1943 and will be at about the same rate. Aircraft construction will continue to demand the largest share of the available supply—perhaps 70 percent; Army, Navy, and Lend-Lease requirements will take most of the remainder; and essential civilian consumption will be allotted probably less than 10 percent of the total.

PRICES

Throughout 1943 the New York open-market base price of primary aluminum remained at 15 cents a pound for lots of 10,000 pounds or more, 99-percent-plus pure ingot aluminum, delivered. Deductions allowed for transportation charges on orders of 500 pounds or more cannot exceed the lowest carload rate of rail freight. Pig aluminum, first quoted late in 1942, has remained at 14 cents a pound throughout 1943 and is subject to the same transportation deductions as primary ingot.

As the result of a renegotiation agreement with the Government, the Aluminum Co. of America announced that on March 1, 1943, considerable reductions would be made in the price of fabricated-aluminum products, which ranged as high as 20 cents a pound for certain types of tubing. The lowered prices reflect savings brought about by increased output, manufacturing improvements, and continued research.

The Office of Price Administration on March 31, 1943, announced that maximum prices for pig aluminum had been set at levels 1 cent a pound below prices of corresponding-grade aluminum ingot. On June 17, in Maximum Price Regulation 2, the Office of Price Administration reduced the maximum base price of secondary-aluminum ingot by 1 cent a pound to the 14-cent level of pig aluminum to assist in continuing the normal flow of aluminum scrap from producers and dealers to smelters. In general, the regulation reduced both scrap and secondary-ingot maximum prices 1 cent per pound below the ceilings previously established. A new classification of "Wrecked Aircraft (Prepared)" was established to meet conditions resulting from the war. Prices for aircraft scrap are based upon the quantity of aluminum recovered after melting it, rather than upon the gross weight before the scrap is melted. To aid in stabilizing the market for secondary ingot, which was not able to compete favorably with

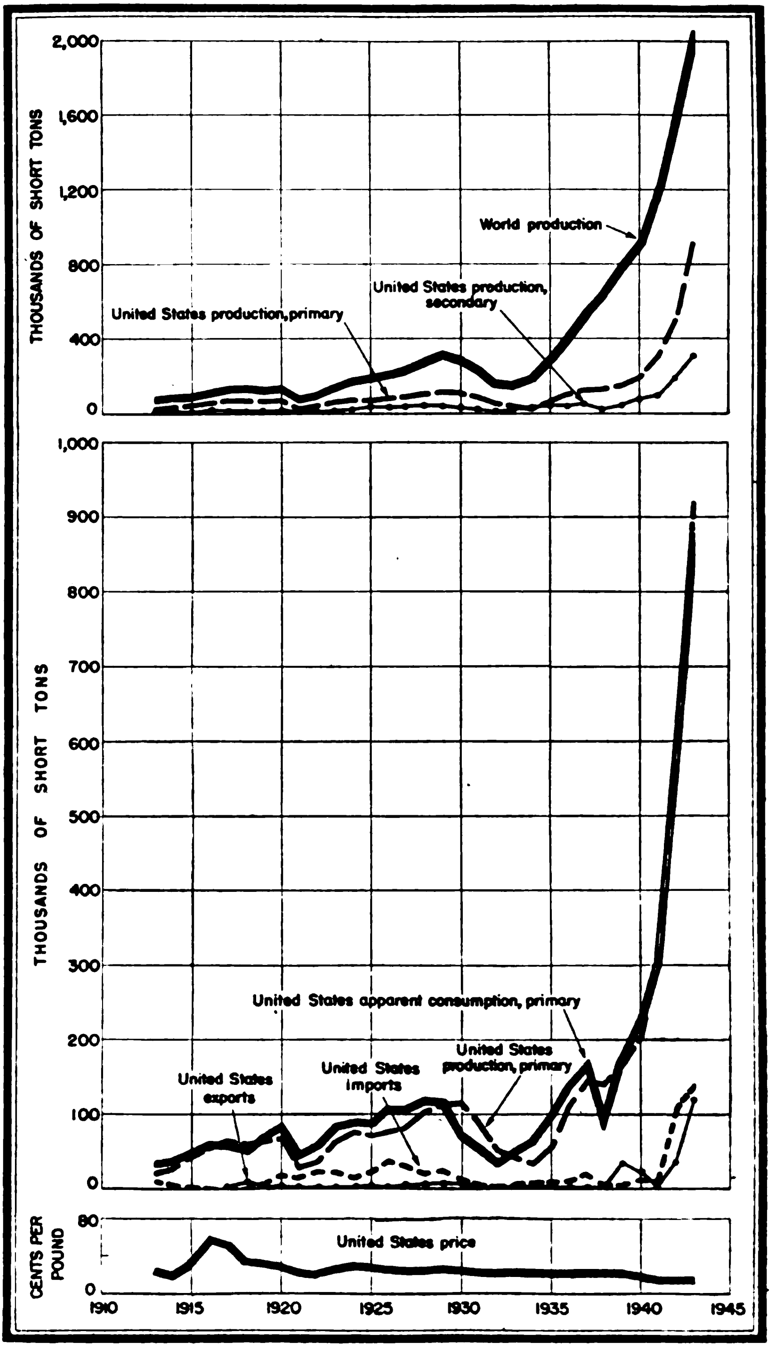

FIGURE 2.—Trends in production, imports and exports, apparent consumption, and average quoted prices of aluminum 1913–43. Price is for No. 1 virgin 98–99 percent at New York through 1929. Thereafter for 99-percent-plus virgin ingot, as reported by American Metal Market.

primary aluminum late in 1943 as total aluminum production increased and surpassed demand, the Office of Price Administration on December 18 reduced ceilings on aluminum scrap and secondary ingot at the producer level by 1½ cents a pound. The new base price for secondary ingot was set at 12½ cents a pound. Since these products had been selling at or below the newly established ceiling levels this regulation in itself resulted in no change in market prices. For the most part, the action was an assurance that a reasonable price differential between primary and secondary metal would be maintained.

FOREIGN TRADE

Imports and exports of crude and semicrude aluminum in 1943 were 21 and 203 percent more, respectively, than in 1942. The value of exports of manufactured aluminum products increased 10 percent, whereas the value of imports decreased 96 percent. Imports, exclusive of scrap, constituted 15 percent of the apparent consumption of primary aluminum in 1943. Of the imports of crude (135,505 short tons), 2 tons came from Venezuela and the remainder from Canada; of semicrude (76 tons), all came from Canada; of scrap (241 tons), 152 tons came from Canada, 58 tons from French Morocco, 21 from Canal Zone, 5 from New Guinea, 5 from Bahamas, and less than 1 ton from Belgian Congo.

Aluminum imported for consumption in the United States, 1941–43, by classes

TECHNOLOGIC DEVELOPMENTS

Probably the most important technologic development during 1943 and early 1944 is the commercial production of alumina from relatively low-grade bauxite. The lime-soda-sinter process mentioned in Minerals Yearbook, 1942, is being successfully used at three of the large alumina plants in the United States and permits recovery of a substantial proportion of the alumina formerly lost in the red-mud residues from the Bayer process when lower-grade ores were used. Before 1940 it was believed that bauxites containing more than 5 to 7 percent silica could not be efficiently treated because of the high loss of alumina. Now, however, ores containing up to 13 percent silica are being effectively used. Low-grade bauxite is put through the regulation Bayer process, and the alumina available to solution by the hot caustic liquors is dissolved out and subsequently precipitated; but the red mud, formerly diverted to waste piles, is now taken to large calcining kilns, mixed with soda ash and lime, and sintered. Following the sintering process the sodium aluminate is leached from the sinter and is precipitated from solution as alumina in the same manner as from the original Bayer liquors. The lime-soda-sinter units do not increase the intake capacity of the alumina plants, but by making it possible to recover more of the alumina contained in the bauxite they increase the alumina output of the plant when relatively low-grade ores must be used. Several future possibilities for this method of recovering alumina which is "locked up" with silica in red mud are indicated. Aside from being used to treat residues from current operations of the Bayer process, it may be used directly on old piles of red mud accumulated in former years, especially at the East St. Louis plant of Aluminum Ore Co. Also, it may be used directly in treating low-grade bauxites without putting them through the conventional Bayer digestors, or it may be used in extracting alumina from high-alumina clays.

Commercial and semicommercial plants are being constructed to produce alumina from alunite, clay, and anorthosite. At Salt Lake City, Kalunite, Inc., has completed its plant to extract alumina from Marysvale alunite by a sulfuric-acid leaching process, although no commercial production has as yet been realized. At Harleyville, S. C., Ancor Corporation is building a plant wherein clay will be treated by a limestone-sinter soda-leach process. Clay and limestone will be crushed together and calcined, releasing carbon dioxide from the stone. The sintered product will be leached with sodium carbonate and filtered to give a filtrate of sodium aluminate. The filtrate then will be treated with the carbon dioxide recovered from the calcining kiln to precipitate aluminum trihydrate. An ammonium sulfate process for producing alumina from clay will be used in a plant now under construction at Salem, Oreg. In this process clay and ammonium sulfate are calcined at approximately 400° C. resulting in the formation of anhydrous ammonium alum and ammonia gas, collected as the carbonate or hydroxide. The calcine is leached with warm water slightly acidified by sulfuric acid to prevent hydrolysis, and ammonium alum is crystallized after the iron has been reduced with sulfur dioxide. The alum is purified by recrystallization and converted to aluminum hydroxide by treatment with the ammonium hydroxide or carbonate recovered in the first step. Ammonium sulfate is recovered from this step and reused for treatment of more clay, and the precipitated aluminum hydroxide is calcined to alumina. At Laramie, Wyo., a plant is under construction to utilize the lime-soda-sinter process in the recovery of alumina from anorthosite.

The Bureau of Mines is investigating several processes for the production of alumina and aluminum sulfate at its various experiment stations. At College Park, Md., the lime-soda-sinter process for the recovery of alumina from clays, anorthosite, and high-silica bauxite is being developed further and studied; at College Park and at Tuscaloosa, Ala., work is in final pilot-plant stage for production of iron-free aluminum sulfate used in the production of a catalyst in the Houdry 100-octane gasoline process; at Norris, Tenn., pilot-plant studies are nearly complete on the production of alumina and ferrosilicon from high-iron bauxites; at Salt Lake City, Utah, further investigations are being carried out on the ammonium sulfate process to be used in the Salem (Oreg.) plant; at Boulder City, Nev., studies are continuing on the recovery of alumina and potassium sulfate from alunite; and at Rolla, Mo., investigation of an acid process for recovery of alumina from high-iron clays is under way.

The continuous casting process of the Aluminum Co. of America, which has been under development for several years, is proving to be of vital importance in the production of large ingots for sheet, plate, bar, and extrusions.[7] Molten metal is poured at a controlled rate into a mold where freezing begins, the ingot being continuously withdrawn from the mold while freezing and cooling are completed. Metal structure obtained by this method is said to be finer and more suitable for subsequent operations than that in ingots cast by older methods. High cost and elaborate installations required are justified by present-day volume production.

[7] Kempf, L. W., Nonferrous Physical Metallurgy: Min. and Met., February 1944, vol. 25, No. 446, p. 104.

Research on the technique of manufacturing small aluminum and aluminum-alloy pieces of high strength and accurate configuration from aluminum powders made by atomization has shown the desirability of employing a mixture of the alloy ingredients rather than prealloyed powder.[8]

Numerous patents were granted during 1943 covering many fields, including protection of surfaces and finishes, cleaning of finishes, bonding rubber and plastics to aluminum, manufacture of refractories from bauxite, aluminum halide and bauxite catalysts, and aluminum sulfate preparation. Many patents also were obtained on recovery of alumina from low-grade bauxite and other aluminous ores and on the manufacture of new aluminum alloys.

WAR MEASURES

In the second quarter of 1943 the Controlled Materials Plan became effective in transitory stage and on July 1, 1943, the former horizontal allotment system—the Production Requirements Plan—was completely replaced (for aluminum, copper, and steel) by the new vertical allotment system. Under the Controlled Materials Plan, requirements for critical materials are adjusted to the available supply through claimant agencies, and the plan provides for the availability at the proper time and place of the quantity and type of materials required to meet approved programs.

During the year Order M–1–i, restricting the uses of aluminum, was subjected to three revisions—on March 13, October 28, and December 4. The effect of the first revision was to tighten slightly the restrictions placed on the metal. Later in the year the order was revised twice in the direction of loosening restrictions, in view of the easier supply situation. Army and Navy uses of the metal were greatly broadened to allow its consumption in any combat matériel. Civilian restrictions were eased to permit use of aluminum in electrical condensers, data-instruction plates, electric motors, foundry equipment, internal-combustion engines, machine-tool attachments, refrigerating and heating coils and fins, scientific and safety equipment, collapsible tubes, trucks, busses and trailers, and other items. On January 25, 1944, the War Production Board announced a new policy permitting the use of aluminum for post-war experiments. Requests for small quantities of aluminum will be granted, provided the experiments can be carried out without diverting manpower, technical skills, or facilities from activities connected with the war effort; all grants of materials in application of the new policy will be carried out within the provisions of order M–1–i.

Full control of anhydrous aluminum chloride to assure proper flow of the material to war consumers was announced by War Production Board in General Preference Order M–287. The purpose of the order is to conserve aluminum and chlorine; it provides that no one may deliver anhydrous aluminum chloride except as specifically authorized or directed by the Director General for Operations.

[8] Cremer, G. D. and Cordiano, J. J., Formation of Aluminum and Aluminum Alloys by Powder Metallurgy: Metal Ind., August 27, 1943, pp. 132–135.

On December 2, 1943, the War Production Board removed the requirement to secure authorization covering delivery of restricted grades of bauxite to manufacturers of alumina or abrasives, or covering delivery of alumina to manufacturers of aluminum or abrasives. The method of securing authorization to deliver bauxite and alumina to persons intending to use them for other than the above purposes was also simplified. With the issuance of General Preference Order M-1-h, as amended, the person desiring specific authorization to accept delivery of restricted bauxite or alumina is required to send his order to the Aluminum and Magnesium Division of the War Production Board, together with a statement of the specific purpose for which the material is to be used.

Restrictions on aluminum paint embodied in Supplementary Order M-1-g, as amended, were relaxed on December 24, 1943. Seven permitted uses of aluminum paint were specified for which no approval of purchase orders is needed. The amended order also forbids the sale of aluminum pigment in amounts of more than 2 pounds and aluminum paint and ink more than 1 gallon to anyone who cannot give a priority of AA-5 or higher. This will permit retailers to dispose of their present stocks in small quantities.

POST-WAR OUTLOOK

Now that aluminum is being produced in more than adequate quantities to satisfy all war needs, attention in the industry is turning increasingly toward the position aluminum will take among the family of metals in the post-war world. With a capacity equivalent to seven times the 1939 production, the aluminum industry must find and keep many new or expanded peacetime outlets if it is to utilize all or even part of the new facilities constructed since the onset of the war. Complex problems will face the industry and the Government at the war's end—disposition of the Government-owned facilities for producing alumina, aluminum ingot, and fabricated products; handling of excess stocks of primary and secondary metal, scrap, and "pipe-line aluminum," all the way from bauxite mines to aircraft factories. A major problem to be reckoned with is the obsolete scrap, which will probably be returned in the form of wrecked aircraft and other damaged battle equipment after the war.

The major influence on the post-war consumption of aluminum will be price. Throughout its history aluminum has shown a downward price trend, and since the period of war preparation the price has dropped from 20 cents a pound to 15 cents a pound in four stages. Pig aluminum is now only 14 cents a pound. With the basic policy of the industry one of lowering prices as fast as technologic advances permit so that the metal can enter new and expanded fields, the post war period may witness further substantial reductions of price. Another influence tending to increase the quantity of aluminum used in peacetime products will be the increased number of workers who will know the technique of casting, forming, and assembling the basic products of aluminum into commercially useful articles.

Civilian aircraft construction after the war, as yet an unknown factor, could consume large quantities of the metal (warplanes are now about 75 percent aluminum by weight). Decrease in weight of automobiles is predicted after the war, much of the reduction to be accounted for by substitution of aluminum in engine blocks, motors, body panels, and other parts. It has been suggested that as much as 500 pounds of aluminum per automobile could be used, including both primary and secondary metal. Highway trucks, streamlined trains, boats, and other forms of transportation are potentially large users of aluminum.

The following table shows the uses of aluminum by industries for selected months during the war years and an estimate after the war:

Uses of aluminum [1]

[In percentage of total use]

	November 1939	December 1940	May 1942	Estimate after war
Transportation (land, air, and water)	29	40	63	34
Cooking utensils	14	6	1	10

Machinery and electrical appliances	15	9	6	12
Building construction	8	5	3	9
Chemical	5	5	5	5
Foundry and metal working	4	23	19	9
Ferrous and nonferrous metallurgy	5	4	2	4
Food and beverage	6	2		5
General miscellaneous	4	1	1	4

[1] Metals, vol. 14, No. 1, July 1943, p. 13.

WORLD BAUXITE AND ALUMINUM INDUSTRIES

Production and consumption of aluminum reached a new high mark in 1943 because of the tremendous demand for military aircraft by the various warring nations. It is expected that this production record will not be greatly exceeded, if at all, in 1944, inasmuch as the various expansion programs are believed to be virtually complete.

[1] Estimated production. Estimates by the authors.

World production of bauxite is estimated to have reached approximately 13,257,600 metric tons in 1943—60 percent more than in 1942 and about three times as much as in the pre-war year 1939. Of the world output in 1943, it is thought that the production in Axis-dominated or controlled territories was 2,801,000 tons or 21 percent of the total and that 10,456,600 tons or 79 percent was under United Nations control.

The aluminum produced in 1943 is estimated to have totaled 2,025,800 metric tons—35 percent more than in 1942 and 181 percent more than in 1939. Of the world output in 1943, it is thought that the production under the control or domination of the Axis in Europe and the Far East was 608,000 tons (30 percent), and under total United Nations control 1,417,800 tons (70 percent).

REVIEW BY COUNTRIES

Argentina.—High-alumina clays containing about 41 percent alumina are reported in large quantities from southern Argentina, near Trelew in Chubut Territory.

Australia.—It was announced late in 1943 by the Ministry of Supply and Shipping that the Commonwealth Government had decided to set aside £A3,000,000 for the establishment of an aluminum industry in Australia. The Victoria Mines Department has done some drilling in the Boolarra district, and two deposits—near Mirboo North in South Gippsland, 80 miles from Melbourne and 20 miles from the state hydroelectric plant at Yallourn—have been recently tested by the Controller of Minerals Production.

At Lake Campion, Western Australia, is an alunite deposit of an unusual type which has created a great deal of interest. It is a lake filling containing not less than 2 million, and probably more than 10 million, tons of alunite mud which is approximately 60 percent alunite. A plant has been constructed using the mud for the recovery of potassium and sodium sulfates at the rate of 5,000 tons a year. The residue from this plant, consisting of 46 percent Al_2O_3 and 37 percent SiO_2, is to be tested for the recovery of alumina in a pilot plant being built at Welshpool.

Brazil.—Latest reports are that the 6,000-ton alumina plant and 2,000-ton aluminum plant at Saramenha, near Ouro Preto, Minas Gerais, being built by the Companhia Electro-Chimica Brasileira, will be in operation during the spring of 1944. The output of this plant at capacity will be about 20 percent in excess of Brazil's normal domestic demand for the metal. Plans for the construction of the 20,000-ton reduction plant near São Paulo, which was to have been jointly financed by Brazilian and United States capital, have apparently been abandoned until after the war owing to difficulties in obtaining needed construction materials. A third plan for a plant at Campos in the State of Rio de Janeiro is forging ahead under direction of a newly organized aluminum company; but this plan likewise will have to wait till after the war for fruition. Brazil is a potentially large producer of aluminum, with its vast bauxite resources and sources of hydroelectric power. Bauxite exports from Brazil in 1943, though small by comparison with potential reserves, increased greatly and were 76,761 metric tons compared with 12,397 tons in 1942.

British Guiana.—Exports of bauxite by the Demarara Bauxite Co., Ltd., and the Berbice Co., Ltd., totaled 1,901,393 long tons in 1943, of which 1,488,858 tons went to Canada, 389,790 to the United States, 22,734 to the United Kingdom, and 11 to Trinidad. The past year has been the most prosperous to date for the bauxite-mining industry, but it is expected that 1944 production and exports will be only about half as large. On January 26, 1944, shipping schedules for the United States and Canada for 1944 were set at 400,000 tons on a B–2 priority and 1,200,000 tons on an A–2 priority, respectively. Imports into Canada and United States probably will be divided equally between British and Netherlands Guiana (Surinam). On February 17, 1943, the governor assented to a bill passed by the Legislative Council amending the Excess Profits Tax Ordinance of 1941 by extending its application to individuals and companies engaged in mining operations. The mineral most affected by the ordinance is bauxite, and in order that this ore might not be disproportionately taxed, another ordinance was assented to on the same day removing the export duty of 20 cents (British Guiana currency) a long ton and reapplying the general export duty of 1½ percent ad valorem.

Canada.—Early in 1943 aluminum, bauxite, and cryolite were placed under formal allocation. Although aluminum had been under direct control since August 1940 the new order called for strict regulation of the movement of the metal and further restrictions on the end-uses of the material. During the year, however, the situation became increasingly easier, and the supply of metal exceeded the demand by the year's end. In January 1944 restrictions on the use of aluminum were relaxed, and the metal may now be sold to the general commercial trade when used in making aluminum rivets, cast-aluminum welding rod, aluminum welding wire, aluminum metallizing wire, and aluminum wire for anodizing tie wire for electrical conductors. Except for such quantities as may be reserved for the Controller, any person may acquire or use aluminum powder or paste as a pigment in making paint. An indication of the way in which both Canadian and United States aluminum production has outstripped demand is that on December 31, 1943, over 60,000 tons of metal were held at the five Canadian reduction plants in the name of the Metals Reserve Co. (United States) and that by March 31, 1944, this quantity had more than doubled in spite of the shut-down of many potlines in United States plants. In addition to this stockpiled material, the exports of aluminum from Canada to the United States totaled 135,503 short tons during 1943. Mr. C. D. Howe, Minister of Munitions and Supply, announced in March 1944 that a reduction in the price of aluminum sold by the Aluminum Co. of Canada, the sole producer, had been effected by agreement between the company and the government. The new price also applies to purchases by the United Kingdom and the United States, but the amount of price reduction was not specified.

China.—According to reliable sources, bauxite was known at Poshan, Shantung, and southern Liao Ning before 1940. Since that time similar occurrences have been found in Yunnan, Szechuan, Kweichow, and Fukien. The most important of these fields is the one in central Kweichow, which contains ore low in silica and iron and high in alumina (65 to 75 percent). The analyses of this ore indicate that a large part of the alumina is in monohydrated form, probably as boehmite, and that the bauxite may be of the terra rosa type. It is thought that most of the bauxite so far discovered in China is of the terra rosa type, whereas that in Fukien belongs to the lateritic type.

Gold Coast.—Production of bauxite in Gold Coast reached a total of over 160,000 metric tons in 1943, far exceeding previous expectations and nearly quadrupling the 1942 output. All exports of this ore are destined to the United Kingdom for use in aluminum production. Production and exports of ore during 1943 indicate that transportation difficulties, which retarded output in 1941 and 1942, have been overcome.

Cuba.—Several preliminary surveys were made in Cuba to determine whether the same type of bauxite exists there as in nearby Jamaica. Reconnaissance indicated that large deposits of this ore probably are not present at the surface, as in Jamaica. Material similar in appearance to the Jamaica ore has proved to be nearly as high in silica as in alumina.

Greece.—The bauxite mines of the Eliopulos Metal Works near Amphissa are reported to have been taken over by the Hansa Leicht Metal Co. and are producing 3,000 metric tons monthly for export to German and Italian aluminum plants.

Haiti.—The Reynolds Mining Corporation announced early in 1944 that exploration in Haiti had revealed bauxite deposits of considerable size and that the Reynolds concern had been granted a concession by the Haitian Government to mine bauxite and other aluminum ores for 60 years. The Haitian ore is said to have different physical properties from American and Guiana bauxite now being used for aluminum production and is very low in silica. It has been named "lescotite" after President Lescot of Haiti by the Reynolds geologists. According to the company, the richest deposit of bauxite was found in the southern peninsula of Haiti, 3 miles from a seaport. It is believed that the ore found here is similar to the recently discovered Jamaica bauxite, which is characteristically low in silica, high in iron, and moderately low in alumina (40 to 50 percent). No announcements have been made as to when these Haitian deposits will be exploited.

Honduras.—Bauxite deposits reported near the Rio Patuca, Department of Colon, have proved to be clay deposits containing at least as much silica as alumina.

Hungary.—According to German reports, the aluminum plant at Ajka will start operations in 1944. This plant, which is being built by Magyar Bauxitbanya R. T. and Incandescent Lamp, Ltd., was to have begun production in 1942 and is designed to produce 20,000 tons of alumina and 10,000 tons of aluminum a year. Ungarische Allgemeine Kohlenbergbau, A. G., of Budapest, has enlarged its carbide and ferrosilicon plants as well as the aluminum works at Felsögall. The company also has opened new mines in Iszkaszentgyörgy and in Nagyvaszonypuszta. Early in 1943 Bauxitproduktions A. G. was formed, with a capital of 1,000,000 pengö, for the purchase and lease of bauxite mines and for research relating to bauxite and other products. The Hungarian press reported late in 1943 that the Bakonyer Bauxite Co., Ltd., formed in 1941 with Swiss capital, will increase its capital from 200,000 to 480,000 pengö. The company has bought all shares of the Aluminum Chippis Industry Co., Ltd., the main shareholder. On the occasion of the 75th birthday of the Hungarian regent, Admiral Horthy, 2,000,000 aluminum coins of the value of 5 pengö each were put into circulation. Previously the only aluminum coins in the country were of the value of 1 and 2 pengö and have been in circulation since 1941.

India.—The Aluminum Production Co. of India, Ltd., at Alwaye, Travancore, is reported to be in continuous commercial production, and the output of aluminum ingot is said to be sufficient to cover wartime requirements in the country. The successful production of aluminum marks the first new large-scale metallurgical development to materialize in India since the outbreak of war and also the completion of works which will rank among the major industrial enterprises of recent years. Aluminum-alloy castings are already being produced on a fairly large scale. With increasing industrialization in India, especially the development of the automobile and aircraft industries and shipbuilding, a heavy peacetime demand for aluminum should be created.

Italy.—Since the invasion of Italy, certain Italian alumina and aluminum plants have fallen into the hands of the Allies, but these plants are small compared with the larger works in the north of Italy, which as of June 1944 are still in the hands of the Axis. At Bussi sul Tirino near Popoli in Pescara Province, the 1,000-ton reduction plant owned by the Societa Alluminio Veneto Anonima (S. A. V. A.) and the 1,500-ton alumina plant of the Societa Industrie e Mineraria e Electrochimiche have presumably been captured by the Allies. A larger alumina plant owned by Societa Prodotti Chimici Nazionale at Aurelia near Civitavecchia has also been captured. (Both latter plants are subsidiaries of S. A. V. A.) No information is available as to the condition in which these plants were found, but it is reasonable to assume that they were damaged as much as possible within the limits of time available to the Germans in their retreat, if indeed they had not already been damaged by Allied air attacks before their capture.

Bauxite deposits have also fallen into Allied hands in Italy, but the bulk of the best-grade bauxite used in aluminum manufacture is found far to the northeast in the Istrian Peninsula, in the Province of Gorizia to the north of the peninsula, and on the islands of Cherso and Lussinpiccolo in the Adriatic Sea adjacent to the peninsula. The bauxite in the areas captured by the Allies is located in Aquila Province (estimated reserves, 6,000,000 tons), Benevento Province (estimated reserves, 2,500,000 tons), and in Foggia, Bari, and Lecce Provinces (estimated reserves, 4,500,000 tons). The bauxite found in Aquila and Benevento is used in normal times for the manufacture of chemicals and abrasives, but in the compartimento of Puglie the ore is used for the manufacture of aluminum.

It is reported that the expansion program of the Societa Edison (Milan), which included the erection of reduction plants at Ferrara and Mantua, has been seriously slowed by scarcity of materials, transportation difficulties, and the generally disturbed state of the country.

Jamaica.—Plans for production of bauxite in 1943 did not materialize on a large scale. A shipment of ore made in the spring of 1943 was tested by an American company and found to be too high in iron oxide to be of value in the production of alumina under present operating conditions. In the face of the relatively easy bauxite situation in Canada and the United States, resulting in the cut-back of production in the Guianas, it is unlikely that any large developments will take place in Jamaica, at least for the duration of the war. Early in 1944 Jamaican Bauxite, Ltd., was formed as a fully owned subsidiary of the Aluminum Co. of Canada, Ltd.

Japan.—The Manchurian Light Metal Co. has reportedly raised its capital from 80,000,000 to 200,000,000 yen and proposes to enlarge its Kwantung aluminum works substantially as well as to resume construction, suspended in 1939, of its plant at Antung. The Showa Co., which produces the largest share of aluminum in Japan, claims to have developed new production methods whereby a 40-percent saving in coal and a 50-percent saving in electric power will result, Recent reports state that the aluminum plant at Takao, Formosa. was bombed in January 1944.

It is very likely that the importation of bauxite into Japan has become more difficult in the latter part of 1943 and the first half of 1944 as American submarines have taken a mounting toll of shipping from the Netherlands Indies. Probably the continued air bombardment of Ponape and Palau in the Carolines has materially cut down imports from those islands as well.

Norway.—In July 1943 the Heroya aluminum plant being constructed by the Germans was bombed just as it was coming into production. Damage is said to have been so severe that the plant cannot be rebuilt until after the war. Of the original ambitious German plans to boost Norwegian aluminum capacity to 244,000 tons and alumina capacity to 202,000 tons, it is believed that only a small part remains. Plans are thought to have been abandoned at all but the projected Sandasjoen alumina plant (85,000 tons annual capacity) and the Tyin aluminum plant (24,000 tons annual capacity). Original Norwegian alumina capacity was about 36,000 tons of metal and 22,000 tons of alumina. Factors contributing to collapse of the Nazi plans were noncooperation of Norwegians, labor troubles and sabotage of machinery, and difficulties with the processes. Inability to obtain some of the necessary equipment from Germany may also have played a part in the failure.

Spain.—The capacity of the Sabinanigo plant of Soc. General Espanola de Aluminia is reported to have been raised to 2,700 metric tons annually. No information is available as to the progress of the 8,000-ton plant planned by Empresa Electro-Mecanica de Córdoba.

Surinam.—Virtually all of the 1,670,000 metric tons of bauxite exported by the Surinamsche Bauxite Maatschappij (subsidiary of Republic Mining & Mfg. Co.) and the N. V. Billiton Maatschappij were sent to the United States and Canada. Owing to the drop in shipping quotas, bauxite production probably will be only about 800,000 to 900,000 tons in 1944. It is thought that production from Surinam and British Guiana will be nearly equalized to divide the economic shock of the cut-back evenly between the two countries. In 1943 the production of the Surinamsche Bauxite Maatschappij was from two mines—the Paranam mine (60 percent of total) and the Moengo mine (40 percent). The Billiton mine is located near the Paranam mine of the former company, and a loading station has been constructed about a mile downstream from Paranam at Smalkalden. All ore shipped by the Billiton company is imported by the United States Government under contract. Dredging operations on the sandbar blocking the entrance to the Surinam River have been progressing for some time to make it possible for larger boats to be loaded up the river.

Sweden.—The alumina plant of A. B. Svenska Aloxidverken at Kubikenborg near Sundsvall is now thought to be operating at its capacity of 6,000 tons a year. The alumina is produced by the Pedersen process from andalusite mined by Boliden Gruv A. B. After the war this plant can be easily converted to bauxite if desirable and then will have a capacity of 8,000 tons a year. Svenska Aloxidverken also has built and put into operation an aluminum-reduction plant at Kubikenborg with a rated capacity of about 2,100 tons of metal a year. Synthetic cryolite is now made by the company at its Brantevik fluorspar mine. Total Swedish metal capacity is now about 4,000 tons a year, including the capacity of the Månsbo works, but it is doubted that production is at present 100 percent of capacity owing to the difficulty of obtaining alumina to make more than about 3,000 tons of aluminum.

Switzerland.—In 1943 the Swiss War Economy Office lifted the restrictive measures on the use of aluminum. The metal again can be used for household articles, packing material, fittings, and other items.

U. S. S. R.—Bauxite deposits are found in the northern and central Urals; the main deposit is at Krasnaya Shapochka, north of Serov on the left bank of the Vagram River. Reserves are estimated at 9,200,000 tons averaging about 56 percent Al_2O_3, 3.5 percent SiO_2 and 27 percent Fe_2O_3. A deposit at Sokolovskoe, 20 miles east of Kamensk, contains an estimated 2,600,000 tons. Other deposits are found at Alapaievsk, and at Resh, but the bauxite is said to be of rather low quality. In the Malofasensk area a recent discovery of bauxite is estimated to have reserves of about 10,000,000 tons. The sites of the Volkhov and Dnieper plants which had a combined capacity of 69,000 tons before the war have been recaptured by the Red Army, but it is believed that the plants have been virtually demolished. It is probable, however, that reconstruction of these works is already under way. No information is available on the several large plants rumored to be operating beyond the Urals.

MERCURY

SUMMARY

From a war standpoint 1943 was a satisfactory year in respect to mercury. When the year began, efforts of the Government were directed toward increasing supplies and reducing requirements to assure the filling of war and essential civilian needs. That these efforts would be successful was evident even in the figures for 1942. The war agencies, however, could not stop short of amply covering all possible needs, which early in 1943 included large and expanding demands for chemical warfare and prospects for a repetition of the substantial orders from the U. S. S. R. Also there was question as to the extent of domestic reserves and the ability of domestic mines to continue the high output rate of the recent past. As a consequence more metal was provided than later proved necessary and in the final quarter of 1943 the industry faced near-record supplies, a sharply reduced demand, and a toppling price structure.

In the first 8 months of 1943 domestic production did not equal consumption requirements. This condition is normal for the United States, as before 1940 production had exceeded apparent consumption in only 4 out of 30 years—that is, 1910, 1916, 1917, and 1931. High prices were the principal factor in bringing about the temporary self-sufficiency of 1940–42. In September 1943 a production excess returned, in October and November output was at a rate exceeding 5,000 flasks a month, and during the last quarter of the year consumption fell to an average of 3,600 monthly. The heavy production in the final quarter of 1943 carried the total for the year to 51,929 flasks, the highest annual amount since 1882. Although consumption lagged in the last 3 months of 1943, it established a new all-time high record of 54,500 flasks for that year. Meanwhile imports were also at a new high annual rate in 1943; and the Russian requirement for metal, which led to the large exports in the 12 months ended August 31, 1943, was not repeated and showed no signs of being repeated. At the end of 1943 the accumulation of mercury in Government stock piles, here and in London, was equivalent to about a 2-year supply at the rate prevailing in 1943.

In the fall the war agencies began to retreat from their former position of encouraging production and imports and discouraging consumption. On September 9, 1943, Conservation Order M-78 was revised to permit greater use of the metal, followed by revocation of the order on February 2, 1944. In September, too, the Metals Reserve Co. canceled its contract with the Consolidated Mining & Smelting Co. of Canada, Ltd., for metal from its British Columbia mine, effective October 9. Mercury was reduced to the W. P. B. group III labor classification during the year, which made it more difficult to obtain needed manpower, for development particularly and for other work at the mines, to bolster the already insufficient supply. The labor problem alone (producers said in October) probably would reduce domestic production 25 to 30 percent within 3 months and after that would cause the closing of most of the mines of the country. At the end of December Metals Reserve Co. announced that January 31, 1944, would be the last date on which it would purchase domestic metal under contracts with "qualified" producers, electing to make the penalty payments provided for in the event of contract cancelations.

Salient statistics of the mercury industry in the United States, 1939–43

[Flasks of 76 pounds]

	1939	1940	1941	1942	1943
Production...flasks..	18,633	37,777	44,921	50,846	51,929
Number of producing mines...	107	159	197	184	146
Average price per flask:					
New York...	$103.94	$176.87	$185.02	$196.35	$195.21
London...	$88.26	$201.10	$194.20	$227.87	$281.44
Imports for consumption:					
Pounds...	265,944	12,971	588,228	2,959,489	3,633,216
Equivalent flasks...	3,499	171	7,740	38,941	47,805
Exports:

Equivalent flasks...	1,208	9,617	2,590	[2] 345	[2] 384
Consumption...flasks..	[1] 20,900	26,800	44,800	49,700	54,500

[1] Apparent consumption.
[2] See discussion of "reexports" under Foreign Trade.

The Army found that it had made too great commitments for supplies of mercuric chloride, and the anticipated return of this material to consumption channels further threatened the already weakened market. The chloride had not been disposed of through the first quarter of 1944, however, because of the desire to prevent unnecessary dislocation to the industry.

The inevitable consequence of the above events was a falling price that gathered momentum as unfavorable market factors accumulated In 1943 the quoted price was $196 a flask at New York until the last week in September. It was $190–$193 at the year end, upheld in the last days chiefly by Metals Reserve contract purchases. By the end of January 1944 the quoted price stood at $130, where it held temporarily. Small lots were reported sold at less than the quoted price.

At a Mercury Producers Industry Advisory Committee meeting, January 29, 1944, producers estimated the amounts of production that would be brought out in 1944 at various price levels as follows: At $150, New York, 46,000 flasks; at $130, 33,000; and at $100, 22,000. At $80 a few mines might operate for a very brief period, but any continued output was doubtful. Estimates were based upon the then current costs of material and labor.

Supplies of mercury in Western Hemisphere sources outside of the United States gained also in 1943, and the new high record rate in Canada more than offset the drop in Mexico from the all-time record for 1942. Production in Canada was 22,487 flasks in 1943 compared with 13,630 flasks in 1942, and that in Mexico totaled 28,321 flasks compared with 32,443. Chile probably increased its output in 1943, but there is believed to have been no noteworthy gain in Peru. Production in the Western Hemisphere makes an impressive record in comparison with that in the pre-war period. In 1943 the countries named and the United States together produced about 105,000 flasks of mercury, which is more than four times the 26,000 flasks recovered by the same countries in 1939. Previous Yearbook chapters have congratulated industry and Government for turning the mercury deficiency of the Allied Powers into wartime self-sufficiency; in 1943, as has been pointed out already, the condition became one of temporary excess.

The nominal surrender of Italy to the Allies in 1943 promised greatly increased quantities of mercury for the victors in the future, but owing to occupation of the producing areas by the German army no metal from that source was immediately available.

Conservation Order M-78.—This conservation order served effectively the purposes for which it was drawn. The controlled consumption combined with increased supplies to relieve the earlier critical situation regarding mercury. Consequently, the provisions of the order were relaxed on September 9 to permit its use for the following purposes, formerly banned, and in the proportions indicated: Marine antifouling paint, 100 percent of base period; preparations for film developing, 100; thermometers (except industrial and scientific), 80; treatment of green lumber, 100; vermilion, 80; wall switches for nonindustrial use, 100; wood preservation, 100. In addition, the amounts of mercury permitted for use in mercuric fulminate for commercial blasting caps were increased to 200 percent of the base period chosen compared with 125 percent in the original order, and the allotment for industrial and scientific thermometers was revised to 200 from 100 percent. The revision to the order removed all limitations on health and agricultural uses. The growing excess of supplies over requirements led to revocation of the conservation order on February 2, 1944.

Metals Reserve Co. domestic purchases.—The provisions of the Metals Reserve Co. for purchasing domestic mercury were outlined briefly in Minerals Yearbook, 1942. When the purchase plan was extended to December 31, 1944, it was specified that "qualified producers" (those who produced not more than 90 flasks of mercury in April 1942) must "contract in writing with Metals Reserve Co. to aid in supplying the increased requirements for war by producing at maximum capacity until December 31, 1944." Metals Reserve was to purchase all or any part of the production of such producers, provided the total for any one did not exceed 300 flasks in 1944, except by special arrangement. Their production, however, could go partly or entirely to others than Metals Reserve. Provision was made for terminating the program within 30 days of notice of the intention to do so on or after December 31, 1943. The greatly improved supply situation led the Metals Reserve Co. to serve notice on December 8 that December 31 was the last date upon which producers could apply for confirmation as "qualified" producers, and the buying program was halted January 31, 1944. The company selected the termination penalty to "Settle in cash for such producer's 'total unfilled production' of mercury on the basis of $20 per flask." Such total unfilled production was the amount of mercury equivalent to the producer's average monthly production for the 6 calendar months preceding the effective date of the termination, multiplied by the number of months from the effective date of termination to December 31, 1944, or, as it eventuated, the average production for August 1943 to January 1944, inclusive, multiplied by 11.

Geological Survey and Bureau of Mines activities.—The Geological Survey maintains close relations with the war agencies and by the end of 1943 had transmitted to them preliminary reports on nearly all mines and districts in the country. The Survey published a report on the Ochoco district, Oregon.[1] It also announced, by press releases, the availability of maps and brief text descriptions of Arkansas quicksilver mines and prospects; the Humphreys and Caddo mines, Ark.; the Helen, Sulphur Bank, and Reed mines, Calif.; and the Chisos, Rainbow, and Viviana mines, Texas. A manuscript report on the Horse Heaven district, Oregon, was placed in open file in Portland, Spokane, and Washington, where it is available for consultation by interested persons. This report is of interest not only because it describes an important mercury district but because it points out a close genetic relationship between mercury deposits and certain kinds of intrusive igneous rock bodies.

The Survey completed field work in Nevada and began to prepare a comprehensive State report. Field work was also completed in the Ochoco, Maury Mountains, Steens and Pueblo Mountains, Brownsboro, Tiller, Trail, and Clackamas districts of Oregon and in the Sulphur Bank, Altoona, and Wilbur Springs districts of California. Detailed examination of mines in the Terlingua district, Texas, begun the previous year, was completed, but aerial mapping was continued into 1944. At the end of the year, geologic field work was still in progress in the Los Prietos and Cachuma districts, California, and many mines in other parts of the State were being periodically reexamined to maintain current information. With the Bureau of Mines, a cooperative exploration program at the Oat Hill mine was opened and continued past the year end. The intensive study of the New Almaden district, begun in 1941, was continued throughout the year. In addition to its geologic studies there, the Survey cooperated closely with the Bureau of Mines in a drilling campaign to test the more promising structures in the New Almaden mine.

The Geological Survey examination of Alaskan mercury deposits, begun in 1941, was continued and expanded in 1943. Sampling exposures by the Bureau of Mines in the Decoursey Mountain area were studied by Survey geologists, and other mapping was done that resulted in discovery of three intrusive stocks but no new mercury deposits. The Cinnabar Creek area in the Holitna and Aniak River drainage basins was studied, and the deposits were found to be of the same type and presumably of similar size and grade as those at

---

[1] Stephenson, E. L., Geophysical Surveys in the Ochoco Quicksilver District, Oregon, a preliminary Report: Geol. Survey Bull. 940-C, 1943, pp. 57-98.

Decoursey Mountain and Sleitmut. A Survey party made reconnaissance studies in the Kuskokwim region in a search for altered intrusive stocks and related sills near which deposits of the Sleitmut type might be expected. The Sleitmut deposits, which had previously been mapped in detail, were reexamined to appraise the geologic results of development by the Bureau of Mines and by the operating company.

During 1943 two Survey geologists were investigating mercury deposits in Mexico in cooperation with the Department of State. One of them examined the deposits at Huitzuco, Guerrero, where the ore contains mercury and antimony in the unusual mineral livingstonite. A report on this district will be published soon as a chapter of the bulletin, Geological Investigations in the American Republics. The other geologist continued his program of mapping the Sain Alto and several other important Mexican mercury districts. To date all his reports have been memoranda to the war agencies.

As previously indicated, in part, the Bureau of Mines in cooperation with the Geological Survey continued its search for mercury in 1943 and explored deposits in Alaska, California, Nevada, Oregon, and Texas by means of mining work, diamond drilling, trenching, and stripping.

Exploration in Alaska continued in the Sleitmut district and at the Decoursey mine, in the former area principally by underground operations and in the Decoursey mine by trenching and stripping. The Bureau also aided in the construction of a landing field at Decoursey, as airplane service is essential owing to the isolated situation of this property.

Explorations were conducted in California on the Guadalupe and New Almaden properties in Santa Clara County and on the Oat Hill mine in Napa County.

The Bureau completed drilling and dump sampling begun last year at the Guadalupe mine. Drilling at the New Almaden was begun in August and at the Oat Hill in November. Both these projects are continuing into 1944 with the object of discovering extensions of previously mined ore bodies.

Work in progress last year on the Bretz-Cordero properties in Oregon and Nevada was also completed.

Diamond drilling was carried on in the Terlingua district, Texas. Although this exploration disclosed no ore, valuable geological data were obtained essential for the guidance of future operations in this extensively mineralized area.

During 1942 and 1943, exploration by the Bureau of Mines developed about 600,000 tons of ore containing the equivalent of 37,000 flasks of mercury.

War minerals reports were released for limited distribution on the following properties in 1943:

Red Devil mine, Sleitmut area, Southeast Alaska; Coso Mercury deposit (Inyo County), Falcon mine (Santa Barbara County), New Almaden mine (Santa Clara County), Guadalupe mine—Supplement (Santa Clara County), California; Bonanza (Hermes) mine (Valley County), Idaho; Rand mine (Elko County), Bretz mine (Malheur County), Oregon; and Cordero mine (Humboldt County), Last Chance (White Peaks) mine (Humboldt County), Nevada; Nonpareil Mercury mine (Douglas County), Black Butte mine (Lane County), Pacific Syndicate mine (Jackson County), War Eagle mine (Jackson County), Bretz Mercury mine dumps (Malheur County) (supplement to report listed under Nevada), Oregon.

Data were also available in the form of memoranda on numerous other properties and areas.

POST-WAR OUTLOOK

In recent years and during the war period there has been a trend away from the use of mercury for certain purposes. There is little reason to expect that the felt industry will return to it after the war. Substitutes for mercury fulminate appear to have gained ground, and a drop in this application may be anticipated in favor of lead azide and other substances. Plastic and copper oxide paints replace mercury oxide for antifouling and may gain in this field. Certain pharmaceutical uses may also bow out to substitutes. On the whole, however, the place of mercury in the industrial future is believed to be assured, at least at former levels. Gains in use in the manufacture of lamps, arc rectifiers, and other electrical apparatus, in instruments and control devices, and perhaps for agricultural purposes are expected to offset the possible decreases indicated. Relative cost, efficiency, and industrial habit will prevent large-scale substitution until mercury is much scarcer than at present. The throwing back on the market of surplus Government materials, however, would temporarily reduce requirements for new metal.

A probable return to pre-war prices or to near that level would cause a sharp decline in the portion of the market supplied by domestic mines.

PRICES

The quoted price for mercury held at $196 at New York, per flask of 76 pounds, from the last week in October 1942 to the last week in September 1943. It then dropped $1, followed by further declines of $3 and $2, respectively, late in November and early in December. The market weakened considerably in January 1944 in anticipation of the discontinuance of Metals Reserve buying at the end of that month. By the last week in January the quotation was down to $130 a flask with nothing in evidence that would cause a noteworthy reversal in the price trend. Throughout the year the ceiling price limitations established by the Office of Price Administration in February 1942 were in effect. Ceiling price provisions were outlined in the Mercury chapters for 1942 and 1941.

As in 1942, there was no evidence of any changes in the price for Spanish and Italian metal. This price was established at $250 a flask, f. o. b. ports of origin, in December 1940. There is nothing normal, however, about the transactions in what would ordinarily be the international market. Germany has been the principal market for Italian and Spanish mercury since the outbreak of war in Europe, and German methods of purchase leave the effectiveness of the $250 price open to question. Purchases by other countries would seem also more apt to be upon the basis of negotiation rather than of a restricted price.

Average monthly prices per flask (76 pounds) of mercury at New York and London, and excess of London price over New York price, 1941–43

Month	1941			1942			1943		
	New York [1]	London [2]	Excess of London over New York	New York [1]	London [2]	Excess of London over New York	New York [1]	London [2]	Excess of London over New York

[1] Engineering and Mining Journal, New York.

[2] Mining Journal (London) prices in terms of pounds sterling are converted to American money by using average rates of exchange recorded by Federal Reserve Board. Official prices, established early in May 1941, were £47 15s. to £48 15s. per flask until August 1942, when they were raised to £68 10s. to £69 15s.

[3] New York excess.

Control maximum prices in London remained unchanged from those during the late months of 1942, at £69 15s. a bottle for over 1 bottle and less than 11 bottles and £69 for larger amounts, ex-sellers' premises in both cases. These prices, however, were approximately £20 higher than those prevailing before August 1942. Higher prices prevailed for lots under 1 bottle and for redistilled grades.

CONSUMPTION AND USES

Mercury has a wide diversification of end uses; actually over 3,000 are known. Its high specific gravity, its fluidity at ordinary temperatures, its electrical conductivity, and the properties of its vapors lead to its use in instruments, control devices, lamps, and other apparatus. The poisonous quality of the metal and its compounds is responsible for their broad use in inhibiting bacterial and parasitic growths. The principal war as well as peacetime use is in the manufacture of pharmaceuticals, and the sharp gains in consumption for this purpose in 1943 stems from the Army's large requirements for prophylactics and antiseptics. Mercury acts as a catalyst in numerous chemical reactions. For a large part of 1943 the principal quantities were consumed as a catalyst in the manufacture of chemicals for chemical warfare use. This use is included under "other" in the accompanying table. The Maritime Commission construction program gave impetus to consumption of mercury in antifouling paint for ship bottoms, which considerably more than doubled in 1943. The Navy reportedly had discontinued the use of mercury paint in favor of plastic paints and cuprous oxide paint before 1943 but used at least some of the mercury product in 1943. Consumption of mercury in calomel for tracers (munitions other than fulminate) in 1943 was cut to little more than one-third of the total for 1942. The use of mercury in fulminate declined about one-fourth in 1943.

Supply of mercury in the United States, 1939–43, in flasks of 76 pounds

Year	Production	Imports for consumption	Exports	Consumption
1939	18,633	3,499	1,208	[1] 20,900
1940	37,777	171	9,617	26,800
1941	44,921	7,740	2,590	44,800
1942	50,846	38,941	[2] 345	49,700
1943	51,929	47,805	[2] 384	54,500

[1] Apparent consumption.

[2] See discussion of "reexports" under Foreign Trade.

Mercury consumed in the United States in 1942 and 1943, in flasks of 76 pounds

Use	1942 [1]	1943 [1]	Use	1942 [1]	1943 [1]
Pharmaceuticals	8,088	14,563	Electrical apparatus	4,550	3,284
Dental preparations	1,198	556	Industrial and control instruments	[2] 3,529	[2] 3,674
Fulminate:					
Munitions	4,146	1,931	Amalgamation	180	24
Blasting caps		1,211	General laboratory use	294	360
Munitions other than fulminate	3,684	1,286	Vermilion	215	185
Agriculture	1,533	1,632	Felt manufacture	20	-------
Antifouling paint	1,220	2,702	Redistilled	[2] 6,175	[2] 5,384
As a catalyst or in the electrolytic preparation of—			Other	[3] 9,103	[3] 11,241
Chlorine	549	691		[1] 49,700	[1] 54,500
Caustic soda					
Acetic acid	1,410	1,995			
Other	1,843	2,437			

[1] The items are on a partial-coverage basis and do not add to the total, which has been increased to cover approximate total consumption.

[2] About half of the quantity shown under "Redistilled" was for use in industrial and control instruments.

[3] Of the quantities shown under "Other," 1,028 flasks in 1942 were for a new chlorine-plant installation and to replace mercury-boiler leakages; 75 flasks in 1943 were to replace boiler leakages. It is deemed inadvisable at this time (May 1944) to divulge details covering other items.

In consequence of revocation of Conservation Order M–78, gains in the consumption of mercury may be expected for the following uses: Industrial and control instruments, electrical apparatus, agriculture, turf fungicides, and wood preservatives.

STOCKS

Consumers and dealers held 13,200 flasks of mercury at the end of 1943 compared with 10,700 flasks at the end of 1942. Meanwhile companies that report mine production monthly to the Bureau of Mines—about 95 percent of the total—had 3,457 flasks on hand compared with 1,377 flasks in 1942. Inventories in Government hands made even more noteworthy gains in 1943, advancing from 27,410 flasks at the beginning of the year to 69,852 at its end. Companies that use redistilled metal only reduced their holdings of metal in 1943 from 1,600 (revised) flasks on January 1 to 1,400 on December 31.

REVIEW BY STATES

In 1943 the accumulated stimuli to domestic mercury production provided by historic peak prices, Government buying, and other aids led to a production record (the highest since 1882) of 51,929 flasks. Producers complained throughout the year of labor shortages and, as in 1942, of the inefficiency of replacement material. The output is remarkable because it was made despite labor and other handicaps. The opening of the New Idria-Alaska (Red Devil) mine, Alaska, on a larger scale in 1943, the attainment of peak annual production at the New Idria, Calif., after more than 80 years' operation, the almost quadrupling of output at the Abbott mine, Calif., the substantial gain at Mount Jackson, Calif., and the almost doubling of large-scale production at the newly opened Hermes mine, Idaho, were the principal factors that erased the losses at many other mines and boosted the United States total.

Mercury produced in the United States, 1940–43, by States

Year and State	Producing mines	Flasks of 76 pounds	Value [1]
1940:			
Alaska	1	162	$28, 653
Arizona	6	740	130, 884
Arkansas	10	1, 159	204, 992
California	70	18, 629	3, 294, 911
Nevada	42	5, 924	1, 047, 778
Oregon	23	9, 043	1, 599, 436
Utah	1	53	9, 374
Idaho, Texas, and Washington	6	2, 067	365, 590
	159	37, 777	6, 681, 618
1941:			
Arizona	5	873	161, 522
Arkansas	19	2, 012	372, 260
California	87	25, 714	4, 757, 604
Nevada	54	4, 238	784, 115
Oregon	21	9, 032	1, 671, 101
Utah	1	19	3, 515

Texas	7	1, 769	345, 326
	146	51, 929	10, 137, 060

[1] Value calculated at average price at New York.

The principal producing mines in 1943 were as follows:

Alaska—Red Devil mine.

Arizona—Gila County, Ord mine.

Arkansas—Clark County, Humphreys mine; Pike County, United States Mercury Company mine.

California—Contra Costa County, Mount Diablo mine; Lake County, Sulphur Bank, Abbott, and Mirabel mines; Napa County, Knoxville and Oat Hill mines; San Benito County, New Idria mine; San Luis Obispo County, Klau and Buena Vista (Mahoney) mines; Santa Barbara County, Falcon (Santa Ynez) mine; Santa Clara County, Guadalupe and New Almaden mines; Sonomo County, Socrates and Mount Jackson mines; Yolo County, Reed mine.

Idaho—Valley County, Hermes mine.

Nevada—Elko County, Silver Cloud mine; Humboldt County, Cordero mine: Pershing County, Red Bird and Pershing mines.

Oregon—Douglas County, Bonanza mine; Jefferson County, Horse Heaven mine.

Texas—Brewster County, Big Bend and Texas Almaden mines; Presidio County, Fresno mine.

These 28 mines produced 90 percent of the United States total; it took 34 mines to produce 89 percent in 1942 and 33 to produce 85 percent in 1941. During 1939, when low prices prevailed, 16 mines produced 88 percent of the total. Of the larger mines listed in 1942 the Idaho Almaden, Idaho, was idle throughout 1943, and the Red Rock and Great Eastern, California, were closed in the latter part of

1943. Of the foregoing list for 1943, the U. S. Mercury mine was shut in November. Many other mines closed following termination of Metals Reserve Co. buying at the end of January 1944.

The average grade of ore treated rose in 1943, against the historic trend. In 1943 the grade was 0.31 percent (6.28-pound ore), compared with 0.25 percent (5-pound ore) in 1942, 0.26 (5.2-pound ore) in 1941, 0.31 (6.2-pound ore) in 1940, and 0.37 (7.4-pound ore), in 1939.

Alaska.—Output of mercury in Alaska in 1943 came again from the Sleitmut and Decoursey Mountain areas. A Gould rotary furnace of approximately 25 tons daily capacity was installed at the Red Devil mine of the New Idria-Alaska Quicksilver Mining Co. at Sleitmut in 1943. This plant was transferred from the Red Elephant mine, Lake County, Calif., where it was built new in 1941. The New Idria Alaska operation was described[2] in 1943. Production at the Decoursey mine continued to be made in a retort. The ore from this mine is high grade and produced 212 flasks from the treatment of 60 tons.

Arizona.—Output of mercury in Arizona declined again in 1943 following a drop in 1942. Only three properties contributed to the total in 1943, however, compared with seven in 1942. The Ord mine in Gila County recovered 316 flasks from treating 4,760 tons of ore. The Pine Mountain mine in the Sunflower district, Maricopa County, made 76 flasks from 2,427 tons of ore in the first part of the year and 137 flasks from 1,863 tons in the latter part, under two managements. Furnaces were used at both properties.

Arkansas.—Arkansas produced 36 percent less mercury in 1943 than in the record year 1942—1,532 flasks compared with 2,392. There were two more producing mines in 1943, but by the end of the year the larger ones were either closed or facing almost immediate shutdowns. Very few smaller mines were operating as 1943 closed. The largest producer was the Humphreys Gold Corporation, operating in Clark County. It furnaced 13,451 tons of ore during the year to recover 691 flasks. Development was discontinued in 1943, and the plant was shut on February 20, 1944. The Caddo mine, also in Clark County, closed on October 2, 1943. All other productive properties in Arkansas were in Pike County; the chief was the U. S. Mercury Co. This company went out of business in November after producing 337 flasks in 1943 from 4,260 tons of ore furnaced. The Arkansas Quicksilver Mines, Inc., operating the Parker Hill and Parnell mines during 1943, was the next most important producer in the State. Other producing mines were the National, Muddy Fork, and Inter-State Trust (Superior), all of which used furnaces. Virtually all of the other production in the district was from small retorting operations.

California.—California again increased its predominant position in mercury production during 1943. The gain from 29,906 flasks (approximating 59 percent of the United States total) to 33,812 flasks (65 percent) was due largely to the outstanding performance of the largest producing mine in the country, the New Idria. Its output gained almost 75 percent during the year and almost equaled that of the five next most important mines in the country. Several other California mines made noteworthy gains, however, including the Abbott, Mount Jackson, and Buena Vista (Mahoney). On the other hand, production decreased considerably for such important producers as the Sulphur Bank, Reed, Klau, and Great Eastern. Seventeen counties contributed some production in 1943, as follows: Colusa, Contra Costa, Del Norte, Fresno, Inyo, Kings, Lake, Monterey, Napa, San Benito, San Luis Obispo, Santa Barbara, Santa Clara, Siskiyou, Sonoma, Trinity, and Yolo.

---

[2] Mining World, New Idria-Alaska Quicksilver Mining Co.: Vol. 5, No 10, October 1943, p. 18.

The Wide Awake mine in Colusa County was operated during the first 6 months of the year; and, as usual, the only active mine in Contra Costa County was the Mount Diablo. The only mercury operation in Del Norte County was the Patrick Creek prospect, which made a small output.

In Fresno County small amounts of mercury were recovered at three localities.

Two operators produced mercury at the old Coso mine, Inyo County, in 1943. The Atlas mine, in the same district, began production in December.

A small production was reported for the Kings mine, Kings County.

Lake County ranked as the third largest producing county in the United States in 1943, with an output of 4,197 flasks. Output came as usual from the old leaders—the Sulphur Bank, Mirabel and Great Western. The Abbott mine, which became a noteworthy producer again in 1942, ranked as the ninth largest producing mine in the United States in 1943. The company sank the main shaft an additional 100 feet and opened the 400-foot level. Operations at the Mirabel [3] mine were described in 1943. The Midway mine made a very small contribution to the county total.

Twelve properties in Napa County, chief among which were the Oat Hill, Knoxville, Aetna, and the Oat Hill Extension, produced some mercury in 1943. This was the fifth largest mercury-producing county in California in 1943; the total output was 1,940 flasks.

The outstanding record of the New Idria mine in 1943 made San Benito County the leading mercury-producing county in the United States, with an output of 14,187 flasks. Although the New Idria has produced mercury for many years and has a recorded production beginning in 1858, its peak for a single year was attained in 1943. It was easily the largest producing mine in the United States and is believed to have been surpassed in the Western Hemisphere only by the Consolidated property, Canada. The Lea-Grant ranked second in importance in the county and had 3 operators during the year. The Stayton mine and 6 others also added to the county total in 1943. Production ceased at the Panoche (Valley View) mine in March, and later in the year the 4-64-foot rotary furnace was moved to the Guadalupe mine in Santa Clara County.

The output of 2,618 flasks of mercury in San Luis Obispo County in 1943 (compared with 2,760 in 1942) was drawn from 6 properties, by far the largest of which was the Klau mine. Development was done on the 450-foot level, the deepest at this mine, and a diamond-drilling program was in progress early in 1944. Important quantities were reported for the Buena Vista (Mahoney), the Oceanic, and the Polar Star. Production came also from the Buckeye and the Rinconada mines. The 50-ton Gould rotary furnace was moved from the Idaho-Almaden to the Polar Star mine in 1943 and began operations late in September. Production in 1943 was from open pits, but development underground was under way at the end of the year.

---

[3] Mining World, Mirabel Quicksilver Mine: Vol. 5, No. 11, November 1943, pp. 18-19.

The Falcon (Santa Ynez) mine was the largest producer in Santa Barbara County in 1943. The Red Rock also made a substantial contribution but closed in September. One other producer in the county was active. Total output for the county dropped from 1,582 flasks in 1942 to 1,229 in 1943.

Santa Clara County produced 1,729 flasks of mercury in 1943 compared with 2,283 in 1942. The outstanding producer in 1943 was again the New Almaden mine. The Almaden dumps and the Guadalupe mine were next in importance, and 4 others contributed smaller amounts. The New Almaden property was recently described.[4] As previously stated, the furnace at the Panoche mine, San Benito County, was moved to the Guadalupe mine, where it had only a few days' run in 1943.

The Empire Canyon (Great Northern) mine was the only one in Siskiyou County that reported production in 1943. This mine changed hands during the year.

Sonoma County produced 4,111 flasks of mercury in 1943, almost identical with the 4,114 flasks reported for 1942. The Mount Jackson had again by far the outstanding amount, followed by the Socrates, Great Eastern, and Culver-Baer. Five other properties contributed to the total. Underground operations on the 500-foot level at the Socrates mine were discontinued, and surface operations were to be given a trial. The Great Eastern mine produced 161 flasks from 4,351 tons of ore in 1943. It did not produce after September and was abandoned by Magee Mercury, Inc., at the end of the year. The Culver-Baer mine produced 146 flasks from 1,389 tons of ore. The Cloverdale mine closed in November, and the Skaggs Springs mine closed in September after producing 30 flasks from 460 tons of ore.

The Altoona mine in Trinity County began to produce in July, and in December its output placed it among the highest 10 producers in the country at that time. From July to December a total of 1,939 tons of ore was treated to recover 280 flasks of metal.

The Reed mine, the fifth largest mercury-producing property in the United States in 1943, made the largest contribution of any Bradley Mining Co. mine in that year. The Harrison mine was the only other mercury producer in Yolo County in 1943.

Idaho.—The Hermes was the only mercury-producing mine in Idaho in 1943, but its output of 4,261 flasks (from the treatment of 71,941 tons of ore) made Valley County the second largest mercury-producing county in the United States. The Hermes mine had the second largest mercury output in 1943. The mining system at this property has been changed from square setting to top slicing, which the company claims has resulted in some saving of manpower and the recovery of more and cleaner ore from the stopes. The property was described in 1943 by Bradley.[5]

Nevada.—Output declined 12 percent in 1943 and the number of producing mines from 40 to 33. The chief mine in both years was the Cordero, Humboldt County, which ranked eighth in the country.

---

[4] Engineering and Mineral Journal, New Almaden Today: Vol. 144, No. 3, March 1943, pp. 59–61.

[5] Bradley, Worthen, The Hermes Quicksilver Mines, part I: Min. Cong. Jour., vol. 29, No. 11, November 1943, pp. 32–34 and part II, vol. 29, No. 12, December 1943, pp. 40–44.

Cordero's output dropped 22 percent in 1943, however. This decline and the shutting of the White Peak mine, which produced 343 flasks in 1942, were the principal factors in Nevada's lowered production rate. The Silver Cloud mine, Elko County, and the Red Bird mine, Pershing County, on the other hand, made large production gains in 1943. The Pershing mine, second in importance in the State, maintained its output at virtually the 1942 rate. The following counties were productive in some measure in 1943: Churchill, Elko, Esmeralda, Humboldt, Mineral, Nye, and Pershing.

Four properties in Elko County produced 842 flasks of mercury in 1943—the Silver Cloud, Butte (Bowers and Rand), Velvet, and Silver Fox. The Silver Cloud mine changed hands during the year.

There were three small mercury operations in Esmeralda County during 1943.

The Cordero mine dominated production in Humboldt County, and five others made small contributions to the total. This county slightly outranked Pershing County as the most important one in Nevada in 1943.

There were two small mercury producers in Mineral County and five of somewhat greater average importance in Nye County. J. H. Smith was the largest producer, operating two properties—the A and B and the M and M.

Except for Pike County, Ark., more mines were producing mercury in Pershing County in 1943 than in any other county in the United States—11 in all. A total of 1,749 flasks was produced compared with 1,525 flasks in 1942. In both years the Pershing mine was the outstanding producer, with 890 flasks from 19,866 tons in 1943 compared with 855 flasks from 18,041 tons in 1942. The Red Bird was second in both years, with production in 1943 much above that in 1942.

Oregon.—With an output of 4,651 flasks in 1943, Oregon maintained its place as the second largest mercury-producing State by a narrow margin; Nevada produced 4,577 flasks. Oregon's total represented a drop of 33 percent from 1942, which in turn was 23 percent below 1941.

One property in Clackamas County and five in Crook County had small mercury outputs in 1943.

The Bonanza mine in Douglas County was the third largest producer in the United States; it held first place in Oregon, with an output of 3,294 flasks from the treatment of 29,509 tons of ore. There are now two plants at this mine, a Gould rotary and a Herreshoff. Development in 1943 consisted of the extension of the shaft and drifts on the 700-foot level. The Buena Vista mine was equipped and treated 300 tons of ore in a Gould rotary furnace in 1943, recovering a small amount of metal.

The Mountain King and two other properties produced mercury in Jackson County. A furnace with a reported capacity of 25 tons was installed at the Mountain King mine in 1942.

The Horse Heaven mine in Jefferson County was the second largest producer in the State. The Axe Handle mine in this county also produced.

Production from dumps and from furnace clean-up operations at the Black Butte mine, Lane County, resulted in the output of 38 flasks of metal.

Both the Opalite and Bretz mines in Malheur County produced in 1943, but their total was considerably under their 1942 rate.

Texas.—Production of mercury in Texas totaled 1,769 flasks, a noteworthy decline from 1942. As in 1942, the principal part of the production came from the Texas Almaden and Big Bend mines of the Texas Mercury Co., Brewster County, and from the Fresno mine, Presidio County. The Esperado Mining Co. began production at the Chisos and Waldron properties, Brewster County, in October but required adjustments to newly installed plants impeded capacity operations. Three other properties in Brewster County made some production during the year.

FOREIGN TRADE [6]

Imports of mercury for consumption in 1943 were 47,805 flasks or 23 percent larger than in 1942; as a consequence, they established a new all-time high record. As in 1942, a substantial part of the metal received was reexported in the same form. This situation is discussed in more detail later. Of the total imports, Mexico supplied 29,457 flasks or almost double the 15,581 flasks from Canada; Chile furnished 2,660 and Peru 107 flasks. Receipts from Mexico were slightly less than in 1942, whereas those from Canada more than doubled and those from Chile almost doubled the 1942 rate. Considerably more mercury would have been received from Canada had not the Metals Reserve Co. contract with the Consolidated Mining & Smelting Co. of Canada, Ltd., been canceled in September 1943. Receipts of metal from Peru were considerably under the original expectations. The Western Hemisphere supplied all of the mercury imported for consumption in the United States in both 1943 and 1942. There was wide fluctuation in the monthly figures on imports, but no trend was evident. More was received in June than in any other month—7,151 flasks—and this large quantity was due partly to the inclusion in it of mercury confiscated by the Mexican Government in 1941. Only 2,437 flasks were received in January, and less than 3,000 flasks each in February, April, and November. Only the low November total of 2,572 flasks is significant, it is believed, because the level of importation was affected by lack of receipts from Canada.

General imports, which may differ considerably from imports for consumption, corresponded almost precisely with them in 1942 and 1943 and were relatively close in 1941. General imports totaled 47,836 flasks in 1943, 38,951 in 1942, and 7,478 in 1941. When there are noteworthy differences between the two classes, general imports furnish a better guide to the amounts of metal actually entering the country.

The movement of antimony-mercury concentrates to this country, which yielded an average of over 1,200 flasks annually for 1940–42, inclusive, was halted in December 1942. This class of imports is not shown separately in foreign-trade statistics.

---

[6] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Mercury imported for consumption in the United States, 1939–43, by countries

Country	1939		1940		1941		1942		1943	
	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value
Canada					59,633	$130,468	562,348	$1,337,640	1,184,211	$3,009,271
Chile							107,091	266,920	202,148	506,710
Hong Kong			3	$6						
Italy	25,528	$29,818	228	316						
Mexico	42,745	61,313	9,698	13,681	520,692	1,171,752	2,288,505	5,122,516	2,238,725	5,010,038
Nicaragua							1,545	3,895		
Peru									8,132	19,934
Spain	197,671	245,613	3,042	3,958	7,903	6,373				
	265,944	336,744	12,971	17,961	588,228	1,308,593	2,959,489	6,730,471	3,633,216	8,545,953

Imports of mercury compounds again had no significance, as is shown by the table that follows.

Mercury compounds imported for consumption in the United States, 1942–43

Compound	1942		1943	
	Pounds	Value	Pounds	Value
Chloride (mercurous) (calomel)	1	$4		
Mercury preparations (not specifically provided for)	1	6		
Vermilion reds (containing quicksilver)	25	10	15	$6
		20		6

Exports of mercury from the last quarter of 1942 through the first 4 months of 1943, as well as in June and August 1943, were dominated by shipments to the U. S. S. R., which were parts of two commitments entered into in 1942. The quantities so shipped were originally classed by the United States Department of Commerce as "exports," but they have been redesignated since chiefly as "reexports" owing to the fact that they consisted mainly of imported metal that was reshipped without changing its form. Some of the original 1943 figures were revised as well as redesignated. The final results show 384 flasks as exports (domestic metal) and 14,852 flasks as reexports (foreign metal). Corresponding figures for 1942 are 345 and 7,461 flasks, respectively. All of the reexported material went to the U. S. S. R. The much smaller exports, on the other hand, went to several dozen countries in both years. The leading destinations in 1943 were as follows: South America took 128 flasks; Asia (except U. S. S. R.) 79; U. S. S. R., 66; North and Central America, 61; Africa, 30; and Oceania, 20. Brazil received the largest amount for any country, with 89 flasks, followed by the U. S. S. R., as already indicated, with 66 flasks.

Commerce records of shipments to the U. S. S. R. in 1942 and 1943 are less than amounts released by Metals Reserve Co. from Government stock piles for shipment to that country (23,578 flasks) and lend-lease reports of shipments (23,485 flasks). It has been impossible to obtain an exact check, and Commerce data are believed to be low by possibly 1,000 flasks.

If Commerce figures require upward revision, exports as well as reexports could be affected.

Mercury exported from the United States, 1939–43

Year	Pounds	Value	Year	Pounds	Value
1939	91, 789	$137, 427	1942	26, 252	$76, 448
1940	730, 877	1, 743, 149	1943	29, 236	88, 842

Mercury salts exported for 1942 and 1943 are shown in the following table. A noteworthy gain is indicated in shipments of mercuric oxide.

Mercury salts exported from the United States, 1942–43, in pounds

	1942	1943		1942	1943
Mercurous chloride (calomel)	22, 844	16, 950	Mercuric oxide (red and yellow)	9, 495	50, 483
Mercuric chloride (corrosive sublimate)	7, 261	12, 422	Mercuric sulfate	15	36
Mercuric fulminate	39, 595	35, 450	Mercuric sulfide	6	25
Mercuric nitrate	477	570	Other compounds	8, 518	7, 388

WORLD PRODUCTION

Although authentic information is not available covering production of mercury in Spain and Italy, the two leading world sources for many recent years, enough data are at hand to indicate that new high records were established for the world as a whole in 1941 and again in 1942, and that the output in 1943 probably was second to production in 1942 and possibly also to that in 1941. The lower rates estimated for Spain and Italy in 1943 are predicated on the large stocks reported to be available in Spain in 1942 and on the belief that Germany was well-stocked with mercury before Allied troops arrived in Italy in 1943 and a battle area was established not far south of the principal Italian mines. As has been pointed out previously in the reports of this series, the increases are due mainly to gains in output in Western Hemisphere sources that have made the Allied Powers independent in regard to essential mercury supplies.

Canada.—Production in Canada exceeded all previous records again in 1943, following new high rates attained in each successive year since the Consolidated Mining & Smelting Co. of Canada, Ltd., began to produce in the Pinchi Lake area of British Columbia in 1940. In 1943 production totaled 22,487 flasks compared with 13,630 in 1942. Following the easing of the mercury-supply situation in the United States, the contract between Consolidated and the Metals Reserve Co. was terminated in September, effective October 9. The Northern Miner of March 23, 1944, points out that the Consolidated mine had developed into the largest mercury mine in North America. In point of production, at least, its total exceeded that of any other producer in the Western Hemisphere in 1943. The annual report of the company indicated that the critical labor shortage restricted development during the year, but stated that several rich stopes were opened and that diamond drilling gave excellent results. It said that the company hoped that the Pinchi Lake property would continue to be

World production of mercury, 1938–43, by countries, in flasks

competitive at the lower market price prevailing at the end of the year. The deposit of the Bralorne Mines, Ltd., on Silver Creek east of Tacla Lake began to produce in the latter part of November 1943. This company has a contract with the Metals Reserve Co. which was on a different basis from the Consolidated contract and was in effect when this report was prepared (May 1944).

Germany.—Ordinarily Germany is the largest mercury-consuming country in the world, surpassing even the United States, and there is every reason to believe that it maintained this position in the recent past (for which actual figures are, however, unavailable). Estimates suggest that consumption for 1940 and 1941, at least, may have been two and one-half times the average indicated annual rate of over 26,000 flasks for 1935–39, inclusive. This high consumption rate was due, according to reports, to new plant installations in which the mercury was used as a catalyst in the manufacture of synthetic rubber, to the conversion of other types of electrolytic cells producing chlorine and caustic soda into mercury cells and to new installations for this purpose, and to the expanded use of mercury arc rectifiers for conversion of alternating into direct current in various plants. Germany may also have increased its consumption for the same applications that showed gains in the United States. (See discussion under Consumption and Uses.) Previous Minerals Yearbook chapters on Mercury have pointed out that there was no reason for Germany to economize in the use of this one commodity, a condition which from the German viewpoint marked a pleasant exception to the usual wartime rule.

Italy.—Information concerning the rate of production in Italy continues to be scant. The nominal surrender of Italy to the Allies has not thus far increased the mercury supplies available to the Allied Powers from this source. Italy is one of the two largest mercury-producing countries in the world, but at the end of 1943 all of the producing areas continued in Axis hands because Rome and the region north were occupied by the German army. Most of the Italian production has been coming from the Province of Sienna, Tuscany, and the chief mines are the Monte Amiata and the Siele. These mines are about halfway between Rome and Florence, close enough to the zone of German and Allied fighting south of Rome so that their high rate of production may have been decelerated. It seems logical to believe that Germany has stored ample stocks of mercury for all reasonable requirements at home, having had ready access to the large resources of Italy and Spain since before the war began. Germany's chief concern in regard to Italian mercury, therefore, would appear to be to prevent stocks of metal or mines in good condition from falling into Allied hands. Fortunately the Allies have little present need for obtaining supplies of mercury from Italy.

The other important Italian mine is the Idria, which is far north near Udine, in the Province of Gorizia. The shipping port is Trieste. Reserves in the Monte Amiata mine are reported to be sufficient for several decades at the present rate of production. Those at Idria, on the other hand, are likely to become exhausted in 10 years or so.

Peru.—Production of mercury in Peru has not increased as planned. The Gould rotary, mentioned in the chapter of this series for 1942, was constructed at the Chonta mine of Panaminas, Inc., in the Province of Dos de Mayo, Department of Huanuco. It commenced production on a small scale in 1943. At the old Santa Bárbara mine a few miles south of Huancavelica, a large plant was under construction early in 1944 following delays caused by difficulties in obtaining a permit to ship the parts from the United States. Ore reserves at this property are estimated at 1,000,000 tons, but they contain only 0.12 percent mercury. Small workings in the Huancavelica area were expected to add 10 to 15 flasks monthly to the country's total.

U. S. S. R.—As indicated in the Mercury chapter for 1942, the U. S. S. R. lost its principal mercury-producing area when the mines at Nikitovka, in the Donets Basin, fell into German hands. To make up the deficit caused by loss of domestic production, coupled with increased consumption due to war demands, the U. S. S. R. purchased over 22,000 flasks from the United States under lend-lease arrangements. Extra efforts were made to increase purchases of Chinese metal for shipments by air. The Soviet authorities had undertaken development of non-Ukrainian fields in an attempt to move their areas of dependency into Asia. Properties already in operation in Kirghizia, Kazakhstan, and Siberia are reported to have capacity for supplying as much metal as was formerly obtained from those at Nikitovka. The Soviet picture is greatly improved over that of a year ago, as a large quantity was received from the United States and the Germans have been expelled from the Donets Basin. There thus appears to be little reason to look for a repetition of large Soviet purchases of mercury in the United States.

GENERAL SUMMARY

Despite pressure for more extended application, the use of virgin tin was again depressed in 1943. Actual consumption—46,253 long tons—was 18 percent below that of 1942; and apparent consumption—less than 32,000 tons—was under that of any year since 1910. At the same time, the physical volume of industrial production rose 20 percent over that of 1942 and was more than three times that of 1919, when the apparent tin consumption exceeded 50,000 long tons. Well planned and directed conservation measures, with effective industry cooperation that made these savings possible, also sharpen the outlines of tin's position in our metal economy. Although it is considered essential for numerous purposes and desirable for many others, the stress of wartime circumstances has shown that tin may be dispensed with or its use sharply limited in some applications. These corollaries of the control programs may have far-reaching future consequences, as outlined in subsequent paragraphs.

Imports of metal and concentrates for consumption were 37,675 long tons (tin content), nearly one-third less than in 1942, as the war in the Pacific cut off access to Far Eastern supplies. Arrivals were about 40 percent of the supply available to the United Nations in 1943. Bolivia furnished 21,048 long tons of tin in the form of concentrates or closely 350 tons more than in 1942, despite unsettled internal affairs and lack of a definite sales-price agreement during the last half year. Belgian Congo supplied most of the remainder, consisting of about 4,100 tons of tin in high-grade concentrates and 11,550 tons of pig tin. Export control remained in effect throughout the year. As usual, the major part of tin leaving this country was in the form of tin and terneplate, which declined one-third from the record volume of nearly 600,000 long tons in 1942.

[3] Figures for 1939-41 cover foreign only; domestic not separately recorded.
[4] Ceiling price, 52 cents.

Although reductions in consumption did not keep step with the contraction in new supply, tin stood in a satisfactory statistical position at the end of 1943. Industry held 23,766 and Government 54,053 long tons of pig tin, and the tin content of ores awaiting treatment amounted to 31,071 long tons. This represents more than 2 years' needs at the current rate of use. There are indications that Great Britain's position improved materially and that of the U. S. S. R. was not as critical as in the preceding year. It thus became possible early in 1944 to divert part of Bolivia's output (about 11,500 tons tin content) of higher-grade concentrates to the United States. Since there are no foreseeable nearby abnormal drains, supply may exceed demand in 1944 in this country and may be nearly in balance for the United Nations.

As in 1942, controlled sales prices were effective throughout the year and held at 52 cents a pound for Straits tin or equivalent grade. The Government Longhorn smelter set prices for five grades (see section on Prices), with the usual trade differentials. The Bolivian price agreement expired June 30, 1943, and up to June 1944 negotiations for a revised and retroactive settlement base had not been productive. The opinion prevails that an eventual revision will be upward. British purchases from Bolivia will be affected likewise. In view thereof and because their sales price has been under that prevailing in this country, it was announced that as of January 1, 1944, the price of standard tin delivered buyer's work would be raised from £275 (effective since December 1941) to £300.

POST-WAR OUTLOOK

The future course of world virgin-tin consumption was the subject of much speculation in 1943. The consensus appears to be that it will not exceed the pre-war (1930-1939) average of about 150,000 long tons. The part or complete displacement of tin from its customary uses and not scarcity seems to have been the basis of that opinion, because production potential is assessed at the pre-war maximum of 250,000 to 260,000 tons. Since the United States usually consumed about 40 percent [1] of the world production the post-war use in this country would have a heavy weight in the world trend.

---

[1] Average consumption in the pentad, 1935-39, was 62,000 long tons and for 8 years between 1927 and 1939 in which actual new metal use was measured, the average was 65,000 tons.

Five tin-bearing products groups took 80 percent or more of domestic consumption in recent years, and the relative amounts assignable to each remained singularly constant. Future trends in these groups are more divergent, but all point toward static or declining use. Tin plate usually took one-half of the new tin supply. Its production probably will increase in the next few years, largely because of growing demand for food in the wake of the United Nations military advances. Exports to our armed forces and for civilian needs also demand standard or high-quality plate. Counterbalancing that rise in metal use is the growing application of thinly coated electrolytic plate and a displacement by tin-free materials, as well as the probable rapid growths in consumption of quick-frozen and dehydrated foods. War time practices doubtless will carry over into peacetimes, especially with the electrodeposited tin plate that alone may reduce consumption 4,000 to 5,000 tons per year, assuming tin-plate production to remain at about a 2-million-ton level.

In the field of bronzes, some contraction from pre-war levels may be anticipated. Shipbuilding—naval and merchant—a large outlet for this class of material, may even decline below that level. Railroad demands are large, but extensive weight economies already effective indicate that little new or make-up tin will be needed. Furthermore, the replacement of the standard bearings by roller and ball-bearing types in railroad and other heavy equipment probably will more than offset any need for additional tin. Enormous expansion of bronze and brass production, first marked in 1940, may also exert a depressing influence on tin consumption because much of the material may be salvageable.

Solder usually occupied second place in use of virgin tin. Experience in 1942–43 has demonstrated that low-tin or tin-free solders may be widely substituted for the usual grades, although special application techniques may be necessary. A potential large requirement for solder (and other tin-bearing materials) exists in the rapidly accumulating demand for automotive vehicles. The satisfaction of that need may be partly completed before a world peace is established, thus modifying the post-war trend, and current experience also has indicated that some tin saving may be effected in this specialized field. In the long run, then, the use of tin in solders appears to be static or even declining.

Among the bearing metals, high-tin babbitts have given way to low-tin war-developed alloys or to virtually tin free substitute metals. The use of thin linings has been extended, and surface treating has lengthened their useful life, both acting to diminish quantity requirements. The use of some substitutes and new practices is likely to persist in the future and will tend to retard consumption.

A substantial quantity of tin, roughly 4,000 tons a year, was used for collapsible tubes and foil. However, a recession in use was noted in recent years. This arose largely by the substitution of aluminum, and it is expected that the trend will not be interrupted. A saving of the order of 3,000 tons a year compared with the pre-war base appears possible. For the major uses the price of tin is relatively unimportant, but in this class of goods and for babbitts and solders it has a considerable influence on the choice between substitutes and tin.

Since it is unlikely that tin will recede from the 50-cent price level for some time, whereas prices of competitive materials may do so, the substitutes will be more strongly entrenched.

In the remaining lesser outlets the usual cyclical variations in consumption will occur. A nearby abnormal increase for a short period to make up for some items that could not be replaced during the war is probable, but on the whole little deviation from recent averages is to be expected.

In sum, war engendered or accelerated decreases in tin uses are of such magnitude and nature that growing industrial production will not be sufficient to effect an upward trend in virgin-tin consumption.

GOVERNMENT TIN PURCHASES

During 1943 purchases of 13,850 long tons of refined tin and 55,000 tons (gross weight) of ore and concentrates were made for Government account. Under the 5-year contract concluded in November 1940, Bolivian producers delivered 47,650 tons of ore and concentrates, and about 650 tons were acquired from French Equatorial Africa and Mexico. Contracts negotiated with African Metals Corporation call for the delivery of all metal produced in the Belgian Congo (less 2,000 tons for Belgium whenever that country may be liberated) and up to 500 tons for African sales. Thereunder, 11,550 tons of refined tin were acquired in 1943. In addition, 6,700 tons (gross weight) of high-grade concentrates were purchased, and the first shipment arrived in June. This material represented an excess of ore production over smelter output, which had been severely hampered by electric power shortage in consequence of drought.

No tin was received from China, but during the year about 1,800 tons were flown to India, and it is expected that about 1,500 tons will reach the United States in 1944. The remainder will be sold in India. About 500 tons of tin were obtained from Portugal through preclusive buying by the U. S. Commercial Co. This agency also concluded—in January 1944—a contract with Williams, Harvey & Co. for the delivery of 20,000 tons of concentrates from the Patiño interests in Bolivia.

The amended price agreement with Bolivian producers expired on June 30, 1943. Producers' demands for a price increase, said to have been as high as 10 cents per pound above the then ruling base figure of 60 cents for contained tin, were unacceptable to the buyers. As a basis for discussion, a price of 63½ cents was suggested. This was not satisfactory to the sellers because the proposed increased smelting charges and penalties for impurities in low-grade material (below 35 percent tin) offset the apparent gain. Negotiations were reopened in December but were again broken off when the Peñaranda government was overthrown near the year end. Nonrecognition of the new de facto government precluded further action, and the status quo was maintained through June 1944. Deliveries, however, have not been interrupted, and it is believed that a new agreement, with some retroactive terms, may be consummated some time after the national election is held on July 2.

CONSERVATION

The achievement of a low in tin use is evidence of the effectiveness of the many control measures directed to that end. During 1943 there were several modifications of limitation and conservation orders, mainly to bring about additional economies or to meet changed circumstances. As electrolytic plate became available, its use was specified for additional products, among them canned milk. It was estimated that the tin requirements for packing evaporated milk in 1942 were around 5,500 long tons in tin plate and about 1,900 tons in solder. Three-quarter-pound electrolytic plate was designated for this use, which would have represented a saving of over 2,000 tons. The effective date of use was deferred from September 30 because test results had not been fully satisfactory and because the can-making machines could not be adapted quickly to the lighter-weight material.

Toward the year end a slight easing of restrictions was noted. They applied mostly to the use of tin and terne plate waste-waste and menders and extended lists of products that might be packed in metal containers. Under an amendment to Conservation Order M-81, beer for use by the armed forces abroad and the Navy offshore may be packed in cans of 0.50 electrolytic plate. Cans for beer first came into prominence in 1935 and were quickly accepted; by 1942, when further use was forbidden, they were a major component of the can manufacturers' output. These and other minor relaxations and the report that rationing of canned goods would be unnecessary by the fall of 1944 prompted the belief that restrictions on tin consumption might then be lifted. The War Production Board, however, made it clear that the conclusion was erroneous.

The practical conclusion of the electrolytic-tinning-plant construction program in 1943 marked the greatest technical advance since the development of the continuous strip cold-rolling [2] process that made it possible. There are now 29 lines at 13 plants, and at rated speed they have a capacity of 48,600,000 base boxes per year or 25 percent more than the total tin-plate production of 1943. Acid baths are used in 17 lines and alkaline in the remainder; all employ flow brightening, and nearly all are equipped to treat the plate chemically during or after quenching. To provide better plant utilization the Weirton Steel Co. employed an electro-tinning line for electro-galvanizing and has reported highly favorable results.

Owing to delays in construction, the volume of electro-deposited plate was still much below that scheduled. It amounted to 19.5 percent of standard coke tin-plate tonnage compared with 3.4 percent in 1942. The average tin weight was 12.2 pounds per short ton and that for standard cokes was 25.8 pounds. Corresponding figures for 1942 were 11.9 and 25.4 pounds, respectively. On the assumption that 40 percent of tin-plate tonnage would be electro-tinned, the tin saving would have been about 4,800 long tons.

In the solder and bronze fields substitutions and down-grading brought about material economies. Although accurate determination is not possible because of lack of complete data and the wide tin range in the various grades, the general effect of down-grading is apparent. For groups of manufacturers who used more than half the total tin (primary plus secondary) contained in solders the approximate tin content declined from 38 percent in 1939 to 29 percent in 1943, and the gross weight of their output dropped more than 25 percent. In babbitt metal the trend was less definite but slightly downward, whereas the gross weight of the output for the same producer groups roughly doubled from 1939 to 1943.

---

[2] The last of the hot-rolling mills, the Washington (Pa.) Tin Plate Co., ceased operation, and the plant was dismantled.

INVESTIGATION OF DOMESTIC TIN DEPOSITS

As a part of their strategic mineral programs in 1943, the Bureau of Mines and Geological Survey continued field studies of tin occurrences. The investigations were concentrated in Alaska, which has produced by far the greater part of the tin credited to the United States.

In the Morelock Creek area the quantity of tin disclosed by drilling was disappointing, and the lode source of the cassiterite was not discovered. The lode source was not found in the Tozimoran Creek area, and investigations were extended into the head of Moran Creek. No significant tin deposits were found in the placers of the Circle Hot Springs vicinity. In the Buck Creek and Cape Mountain areas near York and Tin City, prospecting, drilling, and mapping were continued. Three small, tin-bearing veins were found. Exploration in the Lost River area of the western Seward Peninsula (see Minerals Yearbook, 1942, p. 736) afforded the most encouraging results, and it was planned to continue the project in 1944.

In the continental United States tin-bearing deposits near Temescal, Riverside County, Calif., and some tin-bearing pegmatites near Rockford, Ala., were explored further. Additional studies were made of the Meek-Hogan prospect in Kern County, Calif. Geological maps and sections of the above-named areas were printed. Potential tin sources in New Mexico and South Dakota were also examined and sampled. Economically minable deposits were not uncovered by the field work.

The Reconstruction Finance Corporation furnished financial aid to operators in Alabama, South Dakota, and Texas. None of the ventures has been successful. The utter worthlessness of a reputed tin deposit in Oregon was the subject of an extensive report by Nixon.[3]

DOMESTIC PRODUCTION

MINE OUTPUT

Domestic production was again insignificant. The increase of 1.9 tons over that of 1942 was due to the acceptance of distinctly off-grade material by the Metals Reserve Co. To stimulate production and provide a ready market at numerous purchase depots in the United States and Alaska, that Government agency issued the following purchase schedule.

For Alaskan alluvial tin ores or concentrates delivered at Purchase Depot in lots of one (1) long ton or more and containing 50% insoluble tin (Sn) or more, Metals Reserve Company will pay sixty cents (60c) per pound, dry weight, of contained insoluble tin (Sn), less a deduction for treatment charges and metal losses as follows:

Insoluble tin assay	*Deductions per long dry ton of ore or concentrates*
50%	$63.00
51%	62.00
52%	61.00

---

[3] Nixon, Earl K., An Investigation of the Reported Occurrence of Tin at Juniper Ridge, Oregon: Oregon Dept. Geol. and Miner. Ind. Bull. 23, 1943, pp. 56.

For each additional increase of one percent (1%) in the insoluble tin assay a further decrease of one dollar ($1.00) will be made in the treatment charge per long dry ton of ore or concentrates.

Within United States tin ores and concentrates, containing eighteen percent (18%) or more insoluble tin, delivered to and unloaded at Purchase Depots, are on the following basis:

Price and Treatment Charges: Payment will be made for the insoluble tin content at sixty cents ($0.60) per pound, less a treatment charge of fifty-seven dollars ($57.00) per dry long ton (2240 pounds) of ore or concentrates containing fifty percent (50%) insoluble tin, with an increase in treatment charge of eighty cents ($0.80) per dry long ton for each one percent (1%) decrease in insoluble tin content below fifty percent (50%) and a decrease in treatment charge of eighty cents ($0.80) per dry long ton for each one percent (1%) increase in insoluble tin content above fifty percent (50%), fractions prorated. This charge is to cover treatment, metal losses and penalties for impurities for ores or concentrates having a combined antimony, arsenic, lead, bismuth and copper content of three percent (3%) or less, in cases where the individual impurity content does not exceed:

Antimony	1.2%	Copper	1.5%
Arsenic	.2%	Bismuth	.2%
Lead	1.2%	Sulphur	3.0%
Zinc	3.0%		

Tin ores and concentrates containing in excess of the above maximum limit of impurities will be penalized as follows:

Penalties for impurities: Combined antimony, arsenic, lead, copper and bismuth —three percent (3%) free, excess at forty-five cents ($0.45) per dry long ton of ore or concentrates for each one-tenth of one percent (0.1%), fractions prorated.

In addition, the impurities shall be penalized individually per dry long ton of ore or concentrates, fractions prorated, as follows:

Antimony—1.2% free, excess at $0.60 for each 0.1% subject to rejection above 2.5%.
Arsenic—0.2% free, excess at $0.60 for each 0.1%.
Lead—1.2% free, excess at $0.60 for each 0.1% (Maximum penalty for lead $10.00 per ton).
Zinc—3.0% free, excess at $0.15 for each 0.1% (Maximum penalty for zinc $10.00 per ton).
Copper—1.5% free, excess at $0.23 for each 0.1%.
Bismuth—0.2% free, excess at $0.45 for each 0.1%.
Sulphur—3.0% free, over 3% to 5% inclusive at $3.00 per ton, over 5% to 10% inclusive at $6.00 per ton, over 10% to 15% inclusive at $9.00 per ton, over 15% at $12.00 per ton.

Quantity: Metals Reserve Company will accept tin ore or concentrates at its Purchase Depots in lots of not less than five (5) long tons.

Rejection: Metals Reserve Company may reject any lot of ore or concentrates which does not conform to the requirements and specifications as herein set forth. In any event, Metals Reserve Company will not accept delivery of ore or concentrates containing less than eighteen percent (18%) insoluble tin. Insoluble tin shall consist of all tin that is *not* soluble in hot hydrochloric acid of 20° B. strength.

Mine production of tin (content) in the United States, 1939-43, by States

Year	Long tons				Value
	Alaska	South Dakota	Other States [1]	Total	
1939	33	0.5	0.5	34	38,100
1940	46	2	1	49	54,900
1941	46.8	1.4	8.1	56.3	65,600
1942	2.8	1.4	2.1	6.3	7,300
1943	[2] 2.4	.6	5.2	[2] 8.2	[2] 9,600

[1] 1939-40: Montana and New Mexico; 1941; Alabama, Montana, and New Mexico; 1942: Alabama, California, Nevada, and New Mexico; 1943: California, Nevada, and New Mexico.

[2] Subject to revision.

SMELTER OUTPUT

The Longhorn smelter output of 20,728 long tons of pig tin was substantially below the expected amount and was about 70 percent of the present rated capacity.[4] During the "breaking in" period the smelter had used much high-grade ore. When the transition to Bolivian ores took place—about March—monthly output dropped to less than half the high of 2,611 long tons in January and remained relatively low for about 6 months. In September it passed the 2,000-ton mark and remained at that level through December. As indicated, the lag was due to the metallurgical problems involved and the lack of sufficient capacity to handle charges heavily burdened with low-grade and highly impure Bolivian ores. The average tin content of such ore received in 1943 was 38.7 percent or little more than half that of the usual run of Far Eastern and Belgian Congo concentrates. Better results in throughput and recovery are anticipated in 1944 owing to improvements in the processing of off-grade material and the acquisition of high-grade concentrates from the Belgian Congo, with a large share of Patiño's Bolivian production that contains about 58 percent tin.

The metallurgical difficulties were reflected in production of three new grades. A list of grades made by the Longhorn smelter with percentage ranges in tin content follows:

3 Star	99.80 and over.
2 Star	99.50–99.64.
Class C	99.65–99.79.
1 Star	99.00–99.49.
Grade F	Less than 99.00.

Shipments were 26,725 long tons, of which industrial users received about 12,600 tons and the remainder was distributed to Government agencies and the Metals Reserve Co. warehouses at St. Louis and Chicago.

Privately owned plants treated tin ores on a small scale in 1943 and recovered 761 long tons of tin in the form of pig tin, and alloys (mostly solder) made direct from the ores. In 1942 the total recovered was 472 tons. Only three companies reported production in 1943—American Smelting & Refining Co., Nassau Smelting & Refining Co., and Vulcan Detinning Co.

SECONDARY TIN

The total recovery of secondary tin was 33,800 long tons in 1943, virtually unchanged from 1942. About 85 percent of the tin recovered was contained in lead- and copper-base alloys, from which it is usually not extracted as metal. In 1943, as a wartime measure, however, the National Lead Co., acting as agent for the Metals Reserve Co., recovered about 40 long tons of the tin from type-metal scrap; and the Tin Salvage Institute, another agent, obtained about 230 tons from collapsible tubes.

Although there was little change in the quantity of tin recovered, there were pronounced quantitive differences in the source materials. The quantity of clean tin-plate clippings, usually the source of most reclaimed metal, dropped more than 25 percent but was more than offset by the increased tonnage of old tin cans sent to detinning plants. Because of the tremendous increase in shipbuilding and armament production, the volume of bronze and brass increased manyfold and counterbalanced not only the smaller quantities but lower grades of white metals available. There was, consequently, an increase of about 1 percent in the recovered tin contained in alloys.

---

[4] Secretary of Commerce Jesse H. Jones announced in December 1943 that $350,000 had been made available to the Tin Processing Corporation for additional equipment. This was said to include dust-precipitation and accessory devices that would improve recovery from low-grade Bolivian ores.

A description of the plant, by R. H. Ramsey, accompanied by photographs and flow sheets, appeared in the Engineering and Mining Journal, vol. 144, No. 6, June 1943, pp. 56–61.

Secondary tin recovered in the United States, 1925–29 (average) and 1939–43

Year	Tin recovered at detinning plants			Tin recovered from all sources			
	As metal (long tons)	In chemicals (long tons)	Total (long tons)	As metal (long tons)	In alloys and chemicals (long tons)	Total	
						Long tons	Value
1925–29 (average)	900	2,000	2,900	7,500	23,100	30,600	$38,034,120
1939	3,600	600	4,200	4,000	22,000	26,000	29,276,600
1940	3,700	600	4,300	4,500	25,200	29,700	33,102,400
1941	4,500	950	5,450	5,300	32,200	37,500	43,722,700
1942	4,700	200	4,900	5,200	28,700	33,900	39,487,700
1943	3,900	200	4,100	4,700	29,100	33,800	39,332,800

Detinning-plant output dropped to 3,900 long tons or 17 percent below the high of 1942. The change was a composite of the decline in tinplate output and of the lighter coatings used on electrotinned plate. The last-named factor will have much greater weight in 1944 in consequence of the expected large increase in electrolytic plate use and corresponding drop in drosses arising from the hot-dipping processes.

The War Production Board announced in February that the program for the construction of 10 federally financed detinning plants had been deferred. Later, however, approval was granted for the erection of a large plant at Birmingham, Ala. It has a reported yearly capacity of 20,000 long tons of cans and was expected to begin operation in February 1944. The used-can salvage campaign attained little better results in 1943 than in 1942. Collections probably did not exceed one-third the potential and were said to be less than half the capacity of the privately owned commercial plants. Tin recovered from old cans was about 1,690 long tons or more than three times the 1942 output. Further details will be found in the chapter on Secondary Metals—Nonferrous.

CONSUMPTION

APPARENT CONSUMPTION

The apparent consumption of primary tin, calculated by adding smelter production to net imports, declined 25 percent in 1943, reaching the lowest level in more than 40 years. This method of reckoning consumption excludes all changes in metal stocks held by consumers and the Government, and in times of extraordinary movement, such as the period 1940–43, may present a highly distorted picture. Frequently, however, basic data for more accurate calculation are unavailable, hence apparent consumption statistics offer the only indicator of long-term trends. The data for 1910–38 were published in Minerals Yearbook, 1939 (p. 680); those for 1938–43 follow. Figures for 1931 to 1941, inclusive, do not include exports of domestic tin;

those for 1942 and 1943 include domestic exports, which were 244 and 398 long tons, respectively.

Apparent consumption of tin, 1938-43, in long tons

1938	49, 494	1941	141, 618
1939	67, 997	1942	42, 512
1940	123, 537	1943	31, 749

CONSUMPTION BY USES

The following tables, prepared from reports made to the Bureau of Mines, show actual consumption of tin measured at the point where it enters the process and where it emerges in the first stage of manufacture. The difference of about 4,000 tons represents losses, tin in scrap, and net changes in the quantity in process. The moderate decline of 6 percent from the 1942 total consumption indicates an approach toward a minimum consumption for essential purposes when industrial output is mainly war matériel.

Consumption of primary and secondary tin in the United States, 1939-43, in long tons

	1939	1940	1941	1942	1943

[2] Not including 2,700 tons in transit or in warehouses.

[3] Not including 78 tons in transit.

[4] Includes small tonnage of secondary pig tin.

[5] Not including 316 tons in transit or in warehouses.

Changes in the tin-consumption pattern noted in the 1942 review were accentuated in major items during 1943. In the use of virgin metal tin plate remained in first place, consuming 47 percent in 1943. The drop of 6,838 tons below the 1942 figure also brought use for this purpose to the lowest recorded in recent years. The increased replacement of hot-dipped by electrolytic plate had a marked effect. Total tin-plate production was 19 percent less than in 1942, whereas tin use declined 24 percent. The continuance of degradation and substitution was again noted with respect to solder. For the first time since 1935, less primary than secondary tin went into its manufacture. Compared with 1942 it was down 27 percent, whereas secondary rose 10 percent and total use went off 9 percent. With increased demand for white-base antifriction metals—about 17 percent—the use of tin increased 27 percent, virtually all of which was in secondary form. The record production (especially of ships, tanks, and motorized field equipment) brought bronze and brass into an entirely new position as tin consumers. From 1927 to 1939 they took little more than 5 percent of the virgin tin in any year; in 1943 they used 24 percent. Usually less secondary than primary metal is employed, but in 1943 the ratio was 1 2/3:1. The quality of secondary tin used was the greatest recorded for any product, and total consumption for the first time exceeded that of tin plate. Since bronzes seldom contain more than 10 percent tin, and every effort has been made to employ the low-content alloys the many-fold increase over peacetime needs in the output of this alloy class is evident, and it appears probable that post-war needs may be met to a considerable extent from salvaged material.

Consumption of tin in the United States, 1941–43, by finished products (tin content) in long tons

Product	1941			1942			1943		
	Primary	Secondary	Total	Primary	Secondary	Total	Primary	Secondary	Total

[1] Primary includes small tonnage of pig tin derived from detinning operations; Bureau of Mines not permitted to publish separate figures.

[2] Small quantity included under "Miscellaneous."

[3] Includes 454 tons of primary and 20 of secondary for Britannia ware and 64 tons of primary and 8 of secondary for pewter.

[4] Includes 9 tons of primary and 2 of secondary for Britannia ware and 2 tons of primary for pewter.

[5] Includes 5 tons of secondary for pewter.

In the remaining use fields the general downward trend that was pronounced in 1942 flattened and probably will stabilize near present levels.

The tonnage of virgin tin consumed was reduced 10,000 tons, but that of secondary was increased 5,000 tons with respect to the preceding year. The net effect was a 6-percent reduction, as the full effect of the wartime controls was felt.

FOREIGN TRADE [5]

Imports of tin concentrates and exports of tin plate were the principal elements of the foreign trade of the United States during the year. Pig tin, which had dominated the import field for many years, gave way both in quantity and value to tin concentrates. As this country was denied access to the normal Asiatic sources by the war in the Pacific, metallic tin imports dropped 55 percent to 12,030 long tons, of which 96 percent arrived from the Belgian Congo. Most of the remainder was acquired through preclusive buying in Portugal.

---

[5] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Imports of concentrates were consigned almost entirely to the Longhorn Smelter at Texas City, Tex. The tin content (25,645 long tons) was 11 percent below the 1942 record of 28,933 tons (revised figure). Bolivia was again the principal source, supplying 21,048 tons compared with 20,750 in 1942 (revised figure). Partly replacing the 1942 high-quality arrivals from the Netherlands East Indies were 4,094 tons from the Belgian Congo and 291 tons from French Africa. Mexico supplied 212 tons of very low grade material.

Foreign trade of the United States in tin and tin concentrates, 1939-43

Year	Imports				Exports of tin (metal)[1] (long tons)
	Tin (metal)		Tin concentrates (tin content)		
	Long tons	Value	Long tons	Value	
1939	70,102	$70,590,764	500	$418,004	2,105
1940	124,810	128,294,410	3,000	2,687,154	2,664
1941	140,873	149,569,328	28,670	27,671,689	1,094
1942	[2] 26,753	[2] 29,311,113	[2] 28,933	21,422,896	[3] 165
1943	12,030	13,089,540	25,645	15,352,275	[3] 1,372

[1] Imported as pigs, bars, etc., and exported as such.
[2] Revised.
[3] In addition 244 tons of ingots, pigs, etc., were exported in 1942 and 398 tons in 1943; accounted for as domestic exports in "exports of miscellaneous tin manufactures."

1942[1]	24,082		1,333	3,230	134	595,020
1943[1]	19,591	27	1,607	50	101	396,550

[1] In addition, 15,153 long tons of terneplate clippings and scrap valued at $474,374 were exported in 1940, 751 tons valued at $43,545 in 1941, 76 tons valued at $4,350 in 1942, and 56 tons valued at $5,253 in 1943; not separately classified before Jan. 1, 1940.

Foreign trade in miscellaneous tin manufactures and tin compounds, 1939-43

Year	Miscellaneous tin manufactures		Tin compounds (pounds)	
	Imports [1]	Exports [2]	Imports	Exports
1939	$20, 106	$1, 098, 140	5	204, 362
1940	12, 429	706, 425	271	131, 019
1941	2, 266	1, 456, 353	7, 224	137, 424
1942	[3] 949	591, 937		117, 191
1943	[3] 2, 425	666, 476		25, 042

[1] Includes tin manufactures, n. s. p. f., tinfoil, tin powder, flitters, and metallics.
[2] Includes tin dross and tin-bearing scrap material other than tin-plate scrap.
[3] In addition, 505,346 pounds of tin dross, skimmings, and residues valued at $63,978 were imported in 1942, and 45,943 pounds valued at $4,595 in 1943.

Tin and terneplate constituted the major export commodities. Foreign shipments receded 33 percent from the 1942 record but remained at an exceptionally high value. A considerable part of the decline is attributable to the anti-U-boat campaign that had progressed far in the reopening of sea lanes and the building of nearly 20 million tons of merchant ships in the United States alone. Among the largest declines were shipments to Argentina, possibly because of our strained relations; to Australia, where tin-plate production was reported to have increased; to Egypt; to Iran, which had probably transshipped a sizable part of its receipts to Russia; and to the U. S. S. R., as it became less necessary to duplicate shipments via the extremely hazardous Murmansk route.

Tin plate, terneplate (including long ternes), and taggers tin exported from the United States, 1942-43, by principal countries

PRICES

The price of tin remained stabilized at established Government maximums or ceilings throughout 1943. In the United States Grade A pig tin (which includes Straits brand), the principal grade sold, was 52 cents a pound, ex dock port of entry or f. o. b. producers' plant. A revised schedule entitled Maximum Price Regulation 17 (Tin), which became effective September 22, 1943, made no important changes in the ceiling but set up a more equitable pricing of all grades and brands not conforming to Grade A specifications. The maximum prices by grades and brands are as follows:

Grade A. 99.80% or higher, meeting specifications set forth in M. P. R. No. 17	52.00c.
Following brands of pig tin will be considered as qualifying as Grade A: Longhorn 3-Star, Chempur, Pyrmont, Straits Trading, O. T. Lempriere & Co., E. S. Coy (Penang), Billiton, Mellanear (Guar. 99.9%), Hawthorne Refined, Banka, Union Min. du H. Katanga, M and T No. 1, M and T Electrolytic Refined, Vulcan American Refined, Vulcan Electrolytic.	
Grade B. 99.80% or higher, not meeting specifications for Grade A, providing arsenic content does not exceed 0.05%	51.87½c.
Grade C. 99.65% to 99.79% and 99.80% or higher, not meeting specifications for Grade A or Grade B	51.62½c.
Grade D. 99.50% to 99.64% (includes Longhorn 2-Star)	51.50c
Grade E. 99.00% to 99.49% (includes Longhorn 1-Star)	51.12½c.
Grade F. Below 99% pure (for tin content) (includes Longhorn No-Star)	51.00c.

The London price of £275 established on December 9, 1941, was unchanged throughout 1943. However, on January 1, 1944, the Ministry of Supply announced an increase of £25 per ton to £300 for metal ranging between 99 percent and 99.75 percent tin content. The prices for other grades will carry the usual differentials. The announcement explained that:

> Since December 9, 1941, there has been a general upward movement in the course of tin in the Ministry of Supply, resulting in a substantial burden on public funds at the present price, and the increase now announced takes account of the present and anticipated level of costs of the supply from the different sources available to the Ministry while the present abnormal conditions in the Far East continue.

Free world prices continued to be nonexistent. In some countries, such as Spain and Portugal, exorbitant prices have obtained because of competition among belligerents.

STOCKS

Total year-end stocks of primary tin plus tin content of the ore supply in the United States in 1943 were 14 percent below 1942. The Government held 80 percent and private industry the remainder. Nearly 60 percent of the quantity held by the Government was in the form of metallic tin and the balance in ores and concentrates. Government stocks of pig tin were depleted 16 percent, and industrial stocks declined 27 percent. Virtually all of the industrial stocks were in the form of metal; only a small quantity was in ores awaiting treatment at privately owned plants. The total quantity on hand at the end of 1943 was equivalent to about 2 years' supply at the rate of consumption in 1943.

During 1943 the Bureau of Mines canvassed tin consumers to determine stocks and use. According to these reports, the consuming industry had 22,900 tons of primary pig tin at plants at the end of 1943, including 13,600 tons held by tin-plate manufacturers. The industry also had 316 tons of primary tin in transit or warehoused in addition to 886 tons of secondary pig tin on hand at the end of the year.

[1] As reported by Commodity Exchange, Inc.

[2] Estimated.

[3] Not available.

[4] As reported to the Bureau of Mines; does not include tin in process or secondary pig tin.

[5] Includes 2,700 tons in transit in the United States and at other warehouses not contained in figures above for "at landings" and "in licensed warehouses."

[6] Includes 78 tons in transit and 84 tons held by jobbers.

[7] Includes 316 tons in transit and at other warehouses and 50 tons held by jobbers..

[8] Exclusive of Government purchases delivered for stock piling or at Texas City smelter.

WORLD ASPECTS OF TIN INDUSTRY

WORLD MINE PRODUCTION

Official tin-production statistics have been available from very few countries since 1939, but it appears probable that total output was even lower than in 1942, which was perhaps not half that of 1941. Production accessible to the Allies was again below expectations, but somewhat greater than in the preceding year, and was approaching a balance with their minimum demands. In the Far East the Allies took the offensive, especially against Japanese shipping, with a probable retardant effect on production.

[5] Estimate includes Rhodesia, Swaziland, Tanganyika, and Uganda.

WORLD SMELTER PRODUCTION

Production from the world's smelters is likewise unknown but was probably above that of 1942. Because of a water and power shortage in the Belgian Congo output decreased about 2,000 tons. In China output may have been below the estimated figure, owing to Japanese air attacks on the Papu (PKMA) smelter and low mine production in Yunnan Province. These changes probably were counterbalanced by the 6,000-ton rise in smelter output of the United Kingdom and the United States.

World smelter production of tin, 1925–29 (average) and 1938–43, by countries, in long tons

INTERNATIONAL TIN-CONTROL SCHEME

Production quotas were unchanged from those set up under the fourth control agreement that has been effective since January 1, 1942. Allowable production at 105 percent of the standard is tantamount to unrestricted output. From some quarters there was criticism of Bolivia's share of 49,106 tons (105 percent of standard), but that country has failed to meet its quota for several years.

A historical review of the formation and activities of the International Tin Committee and of the buffer stocks appeared in the August–October 1943 issues of Tin and were reprinted in American Metal Markets of September 16, October 30, and November 13. The United States Department of Justice, Antitrust Division, according to newspaper reports in late July, was "looking into" the monopolistic aspects of the tin cartel. The Senate Subcommittee on War Mobilization of the Committee on Military Affairs published, early in 1944, a study of materials from the files of the U. S. Department of Justice relating to activities of cartels and monopolies.[6] A reference to the International Tin Committee is carried on page 24.

In reaction to the not fully favorable future outlook for tin the Tin Research and Development Council, an auxiliary of the International Tin Committee, prepared plans for long-term research and propaganda. The tentative scheme, according to reports, envisaged a 10-year development period with annual average expenditures of about £300,000. Broad research and semicommercial scale studies were included, as well as technical press propaganda and the establishment of 10 service bureaus in important tin-consuming countries.

---

[6] Economic and Political Aspects of International Cartels, a study made for the Subcommittee on War Mobilization of the Committee on Military Affairs, U. S. Senate, 78th Cong., 2d sess., Monograph 1 Government Printing Office, Washington, 1944, 82 pp.

REVIEW BY COUNTRIES

Australia.—Tin output in Australia was considerably below expectations, with only about 2,800 tons produced in 1943. Manpower and materials shortages have been assigned as causes, but in all probability lack of economically minable resources has been the primary reason. The Commonwealth Government, as well as that of some of the States, provided financial and other assistance. The Government has acquired the mine and plant of the Mount Bischoff Tin Mining Co. in Tasmania, which resumed operations upon a compulsory basis. A dredge that had previously operated in Victoria was acquired by the Tasmania controller of mineral production for alluvial mining in the Ringarooma Valley.

Belgian Congo.—Although it had been expected that 21,500 tons of tin in ore would be produced in 1943, the mine output of the Belgian Congo was 18,000 tons in 1943 compared with 16,800 in 1942. Mining was retarded owing to the driest season on record, lack of labor and materials, and some reluctance of the tin-gold producers to change over completely to tin mining. At some of the mines lower-grade material was being mined in 1943.

The United States imported 11,550 tons of metallic tin from the Belgian Congo in 1943 (11,224 in 1942) and 4,094 tons in ore and concentrate. None was lost at sea in 1943 through enemy action, but a cargo of metallic tin was lost as the result of a marine accident in February.

Exports of metallic tin from the Belgian Congo to African destinations have been about 490 tons annually.

Bolivia.—Bolivia exported concentrates and ore containing 40,312 long tons of tin in 1943 compared with 38,293 in 1942, 42,200 in 1941, and 46,343 in the peak production year 1929. The United States was the destination of 20,580 tons, and the remainder went to the United Kingdom. Patiño, the dominant producer, supplied approximately 50 percent of the country total—an increase of 14 percent from 1942. Under a 10-year contract, the Patiño concentrate is shipped to England, but 20,000 tons are to be diverted to the United States in 1944. Production by the Hochschild interests increased 5 percent to 26 percent of the total, with the remainder provided by Aramayo, medium and small producers. The decline in the shares of the last-named group was due in part to exhaustion of some ore bodies, labor shortage, and marked rises in labor and material costs.

The complete dependence of Bolivia on tin mining as a source of revenue was emphasized by the maintenance of production in spite of political unrest. Considerable bitterness followed the Catavi outbreak of December 1942 and was not lessened by the general conclusions of the joint Bolivian-American investigatory commission that labor conditions and wages were substandard. Peñaranda's government was severely criticized by leaders of the Nationalist Revolutionary Movement (MNR) and led to the resignation of his cabinet in September. About December 20, 1943, the government was seized by a military coup d'etat and a new regime headed by Major Villaroel and leaders of the MNR took its place. In view of the former friendliness of some of the junta members with German commercial interests it was generally believed that the new government was strongly tinged with Fascist or Nazi ideologies. This was sharply denied by Major Villaroel, but after study of the situation nearly all the 21 American republics withheld recognition of his government. The revolutionary Argentine Government was the principal exception and accorded recognition on January 3, 1944. A general strike at the tin mines took place April 19, 1944. The miners were requested to return to work by Major Villaroel. On April 28 it was announced that a "vast revolutionary plot" had been put down, ringleaders were arrested, and the country was declared in a state of siege until a national presidential election could be held in July. During May a special United States commission was dispatched to study and report on the situation. Shortly thereafter about 80 Axis supporters or agents were sent to the United States for internment, and late in June, the State Department recognized the de facto government.

The United States agreement to purchase tin at 60 cents per pound f.o.b. Chilean or Peruvian ports expired June 30, 1943. Negotiations for a new base, expected to be about 63½ cents, were interrupted by the change in government but probably will be resumed after the July 1944 elections. Shipments of concentrate were continued throughout this period, with settlements subject to retroactive revision being made upon the former basis.

Patiño and Hochschild have taken steps to increase production by introducing new methods to improve recovery. At Cerro de Potosí, Hochschild will employ a process developed by U. C. Tainton; and at the Centenario property at Catavi, Patiño will use the sink-float process. These installations may not, in the long run, bring about increased output, but they should retard decline through higher recovery.

British Malaya.—Other than reports emanating from Japanese sources, nothing is known of conditions in Malaya. The Japanese have claimed that mechanical excavation was in progress and that smelting had been resumed at Singapore and elsewhere. Exploitation of the vast tin deposits of southeastern Asia by the Japanese, however, now appears improbable because of lack of machinery, transport, and markets. The subserviency of Thailand alone assures it currently of a supply greater than it can consume. With additional tribute wrung from Malaya and the Netherlands Indies tin has lost its economic status. Color is lent to this belief by an announcement from Radio Hilversum, reported in the Mining Journal (London) of September 25, 1943, that the tin price had been reduced from 830 to 430 yen per metric ton. In the early months of 1944 the Japanese position began to deteriorate rapidly. American forces moved westward in the Pacific to the Mariana Islands, and our submarine and aerial attacks made great inroads on their shipping. Meanwhile Allied forces acting in the Indian Ocean raided the Andaman Islands and the western tip of Sumatra and penetrated the Malacca Straits.

Notwithstanding these offensive successes, the ultimate dispossession of the Japanese from Malaysia is likely to take several years, which means that the United Nations may not ease their tin-restriction programs as yet. Somewhat more optimism apparently prevails among Malayan operators. Many of the companies have set up their head offices in London, and the Malayan Chamber of Mines there started preparation of rehabilitation plans. At the same time, in anticipation of the probable Japanese devastation of mines and works, attempts are being made to have the Government bear a heavy share of the reconstruction costs.

Canada.—Electric smelting of the Consolidated Mining & Smelting Co. Sullivan-mine tin concentrates at Kimberly, British Columbia, was continued in 1943 at about the same rate as in 1942. The product of the smelter averages 99.647 percent tin and enters the market as Tadanac brand. The smelting method used has been described by Jones and Thunaes.[7]

The Consolidated Co. made some explorations in the Yellowknife area, about 700 miles north of Edmonton. It was reported that some pegmatite dikes carrying coarse cassiterite had been found.

Rigid tin conservation has been practiced in Canada. Direct and indirect war uses took 60 percent of current consumption. With the Sullivan production and maintenance of restrictions, it was estimated that all needs could be met for 2 years without importation.

China.—The production of tin in China in 1943 has been estimated at 5,000 tons. Exports, which have been greatly reduced since transportation over the Burma Road was disrupted, have been limited to the quantity that could be flown out to India. The United Air Transport Service reported in July 1943 that in 8 weeks 47 tons of tin, 70 tons of tungsten, 70 tons of silk, and 32 tons of pig bristles had been flown from China to India. It was reported that the U. S. S. R. had not agreed to the reopening of the ancient caravan route through Sinkiang to Russian Turkestan.

In the provinces of Kiangsi and Kwangsi tin mining has been severely affected by Japanese army occupation of all important industrial centers early in the war, very high transportation costs, scarcity of labor, and unfavorable exchange rates.

There are two modern smelters in China, one at Kochiu, Yunnan, and one at Papu, Kwangsi. The combined capacity of these plants has been given as great as 14,000 tons of highly refined (99.8 to 99.95 percent tin) metal annually—adequate to treat all tin ore produced in China. The Papu plant, which is the smaller of the two, treats all the ore from Kwangsi, Kiangsi, and Hunan (normally about 3,500 tons of metal). The Japanese bombed this plant, but since then it has been safely housed in a limestone cave.

Germany.—Although Germany is known to have received substantial quantities of tin from Portugal and perhaps from Japan, there is some evidence of a developing near-famine condition. Virtually all tin-bearing materials throughout controlled areas have been confiscated, and complicated metallurgical processes have been employed to recover tin from bell metal, bearing metals, liquation residues, and many low-content materials. Also, in the latter part of 1943 the tin-plate shortage became so acute that all orders for it had to receive a special approval from the Deputy Reich commissioner for Iron and Nonferrous Metals. Canning has been maintained partly by using bonderized black plate, glass, and other substitutes for cans, very few of which have been available for civilian packs. In spite of this apparent scarcity, it was reported late in the year that a few thousand cases of tin plate of Belgian origin had been imported by Portugal for packing sardines.

---

[7] Jones, E. L., and Thunaes, H., Electric Furnace Smelting of Tin Concentrate from Sullivan Ore: Canadian Min. and Met. Bull. 382, February 1944, pp. 35-43.

Tin destined for Germany was reported among the cargoes of three blockade runners reported sunk by our Navy in the South Atlantic on February 4, 1944. The British Parliamentary Secretary to the Minister of Economic Warfare also reported that four German cargo ships en route to Europe from the Far East had been sunk during first part of 1944 carrying approximately 10,000 tons of tin. Japan possibly shipped as much as 20,000 tons of tin to Germany in 1943, but it is doubtful if any great part reached its destination, as at least 11 blockade runners have been reported sunk.

Italy.—German propaganda statements have claimed that they were better off by capitulation of Italy, as far as metal supplies are concerned, since they had been supplying Italy from 10,000 to 15,000 tons of copper annually, together with 1,000 to 2,000 tons of tin and 2,000 to 3,000 tons of nickel. The concentrating plant at the Monte Valerio mine, Tuscany, produced about 200 tons of tin annually, and the Canale Serci tin mine in Sardinia has been operating on a small scale.

Japan.—It is doubtful if Japan has continued to work its own low-grade mines in view of the wealth of metal and ore acquired after the occupation of Penang, and subsequently. With the presently demanded increase in war production it appears even less likely now.

It has been surmised that Japan has shipped as much as 10,000 tons of metal to Russia. Sizable quantities were destined for Germany, but many of the blockade runners were intercepted or sunk en route.

Mexico.—Mexico has not been an important source of tin. Production was 426 tons in 1943 compared with 364 in 1942. Total production between 1800 and 1940 has been estimated[8] at 5,315 long tons (73 percent being credited to the final decade of the period). Extremely small placers mined entirely by hand methods, which cannot be worked profitably with machinery, have been the chief source of tin in recent years. Vein mining has been infrequent, and several attempts on a large scale proved unprofitable.

Netherlands East Indies.—No reliable information has been available from the Netherlands East Indies, since their occupation by the Japanese. However, not much tin can have been produced in 1943, as operations probably were confined to scant output of native laborers using primitive methods. According to a Tokio broadcast, tin dredges had been dismantled and scrapped for steel. Preparatory work for rehabilitation of the tin mines after the Japanese have been driven out has been temporarily assigned to a group of Netherlands East Indies Government officials evacuated from the islands before the invasion. It is planned to build completely self-contained, Diesel-driven dredges in the United States and to tow them across the Pacific, as has been done with dredges from Holland. As soon as the Japanese are driven out the dredges would be put to work on off-shore deposits. "Sea tin" formed part of the production of Singkep, and it also exists off the coasts of Banka and Billiton.

Nigeria.—By intensive working of higher-grade and most accessible deposits Nigeria produced 13,680 long tons of tin in 1943 (12,711 in 1942). An abnormally dry season, and to a lesser extent labor shortages, adversely affected production during the latter part of the year. The water shortage handicapped production in two ways: It limited washing in the pits and cut hydroelectric power output so severely that current was rationed. To ameliorate this situation the Nigerian Government has begun construction of a new dam on the Tenti River. The work has been well advanced, so that a substantial water reservoir will become available for use in 1944. If enough water and some additional equipment are available, it is believed that a maximum output of about 14,800 long tons can be attained in 1944.

---

[8] Foshag, William F., and Fries, Carl, Jr., Tin Deposits of the Republic of Mexico; Geologic Investigations in the American Republics, 1941–42: Geol. Survey Bull. 935–C, 1942, pp. 99–176.

Proved and probable reserves of tin ore are reported to be sufficient for 7 years at the wartime rate. Important new discoveries are unlikely, although improved operating technique and intensive development work might well extend the life of some of the properties.

Portugal.—Production of tin in Portugal was 3,058 tons in 1943 compared with 2,381 in 1942. Exports of metallic tin were 1,909 tons in 1943 (1,522 in 1942). Shipments to German-controlled European countries amounted to 60 percent of the total in 1943 (48 percent in 1942). Members of the British Parliament were much concerned with this traffic which persisted despite preclusive buying by British and American agencies. In response to questioning, the Secretary to the Ministry of Economic Warfare replied that every effort was being made to impress on the Portuguese Government and the people the importance attached to the matter by the British Government. An Anglo-Portuguese alliance of several hundred years standing prevented the exercise of forceful diplomatic and economic pressure, but some improvement in the situation was noticeable in the spring of 1944.

Under a commercial agreement concluded between Portugal and Spain, Portuguese exports were to include 400 metric tons of tin in 1943. The Portuguese-American Tin Co. has continuously operated its mine without interference other than Portuguese Government orders and restrictions as to sales and prices of tin.

Spain.—Plans of the Peñarroya Co. include the production of metallic tin and its alloys at its carborundum works at Peñarroya—Pueblo Nuevo. It is proposed to treat ores and products containing tin in single-phase arc-type electric furnaces. Calcium stannate obtained as a byproduct of lead smelting will be treated in the electric furnace to obtain bearing metal.

Union of South Africa.—The Zaaiplaats Tin Mining Co., Ltd., milled 41,420 tons of ore and recovered 192.5 long tons of concentrate averaging 71.22 percent tin, during the year ending July 31, 1943. The smelter handled the entire mine output of the Union, Swaziland, and South-West Africa and produced more than 670 long tons of metallic tin. Plant performance and quality of metal were said to be better than in preceding years. The output of the Zaaiplaats and Bulawayo smelters exceeded local needs, and shipments to India were reported.

U. S. S. R.—The Russian tin situation is not definitely known. Presumably it is less critical than in the past 2 years, since direct tinplate exports from the United States declined about 20,000 tons (40 percent) from 1942. In that year 28,000 long tons also were reported shipped to Iran, but the eventual destination was probably the U. S. S. R. In 1943 there was no like movement. These changes also reflect the newly effected Allied control of sea lanes, as well as the possibility that some pig tin may have been obtained from Japan, with which Russia was still on a peace footing in June 1944.

Sketchy reports of tin discoveries have been made again, but no information on locality or extent of the deposits was forthcoming.

United Kingdom.—There has been no disclosure of the quantity of tin stocks in the United Kingdom, but the supply for essential needs has been satisfactorily maintained, with consumption cut to 50 percent. Tin ores from Bolivia and Nigeria (and some metal and ore from Portugal) have been imported in sufficient quantity on reduced smelter requirements. Part of the Bolivian ore scheduled for shipment to the United Kingdom will be diverted to the United States in 1944. Since the beginning of the war very little information has been disclosed regarding production by the Cornwall tin mines, but output is believed to have been around 2,214 tons in 1943. The outlook for tin mining is not good, unless prices are put in line with increased costs (of coal and labor principally) or Government assistance continues. There are four important properties—Geevor, South Crofty, East Pool, and Castle-an-Dinas. The Cornish Tin Mining Advisory Committee has petitioned the British Government for post-war assistance, without which continued existence seems doubtful.

For the greater part of 1943, production of tin plate in Wales fell steadily, reaching the lowest figures in history. However, output increased in the final quarter, and by the end of the year a substantial number of orders were in hand for first quarter of 1944. Manufacturers have agreed to a redundancy scheme whereby at least 30 percent of the old mills will be sterilized. Approval of the scheme by the Board of Trade is awaited. A small quantity of electrolytic tin plate has been produced in a pilot plant but did not find a very ready market. Nevertheless, it has been reported that Richard Thomas & Co., Ltd., which has a continuous cold-strip mill, has ordered an electrolytic tinning unit from the United States. It is expected to reach the production stage in 1944. Bonderized plate has been developed, but its use for food cans has not made much headway.

ARSENIC

GENERAL STATEMENT

Domestic production of white arsenic increased nearly a tenth in 1943 compared with 1942; and imports, comprising a third of the new supply, were steady.

For the first time in nearly 20 years production of ores mined chiefly for their arsenic content was reported as the United States mine at Gold Hill, Utah, was reopened. The mine has been inactive since 1924–25, but during the last 4 months of 1943 several thousand tons of arsenopyrite ore averaging about 23 percent arsenic (As) were shipped monthly to Midvale, Utah, for recovery of arsenic.

Stocks held by producers and the Government were halved to help meet a record consumption. The quoted price of white arsenic remained at 4 cents a pound throughout 1943. Arsenic was placed under allocation control by the War Production Board May 22, 1942 (Order M–152). Military contract cancellations early in 1944 considerably reduced arsenic requirements, which, together with the expected increase in production at Gold Hill in 1944, should bring supply and requirements more nearly in balance.

DOMESTIC PRODUCTION

White arsenic production in the United States was 9 percent greater in 1943 than in 1942 but 4 percent less than in 1941. The output, principally a byproduct of copper and lead smelting, although augmented in 1943 by the treatment of rich arsenical ores, was by the American Smelting & Refining Co. at Tacoma, Wash., El Paso, Tex., and Murray, Utah; by the Anaconda Copper Mining Co. at Anaconda, Mont.; and by the United States Smelting, Refining & Mining Co. at Midvale, Utah. Canadian cobalt-nickel concentrates are treated by the Ferro Enamel Corporation, Cleveland, Ohio, in making calcium arsenate and by the Shepherd Chemical Co., Cincinnati, Ohio, in making sodium arsenite.

Government program.—The Metals Reserve Co. in March 1943 appointed the United States Smelting, Refining & Mining Co. its agent for the purchase and treatment of arsenopyrite from the United States mine at Gold Hill, Utah, to yield 47,000 short tons of crude arsenic within 5 years after completion of facilities. Two properties at Gold Hill (the United States mine of the United States Smelting, Refining & Mining Co. and the Western Utah Copper Co. mine) have been important producers of arsenical ores in the past, and ore reserves are estimated to exceed several hundred thousand tons. The two mines are credited with a production of 35,444 tons of ore in 1924 and 3,045 tons in 1925, but no production of arsenical ores has been recorded since 1925 until the United States mine was reopened in September 1943. During the remainder of 1943 the company shipped several thousand tons of ore each month to the enlarged arsenic plant at Midvale. The ore is chiefly arsenopyrite, with minor quantities of scorodite, and in 1943 averaged about 23 percent arsenic (As). The nearby property of Western Utah Copper Co. was not reopened during 1943, although plans were proposed to resume shipments in 1944. During the year, however, several hundred tons of arsenopyrite ore that had been mined in 1924–25 and held in stock at the Murray plant of the American Smelting & Refining Co. were treated at the arsenic roaster unit at that plant, thus augmenting the output of arsenic.

Through arrangements made by the Metals Reserve Co. in June 1943, the American Smelting & Refining Co. planned to produce 10,000 tons of crude arsenic from flue dust supplied by Getchell Mine, Inc.,[1] Red House, Nev., and 1,568 tons from speiss furnished by Richmond Eureka Mining Co., Eureka, Nev. The former project yielded 432 tons and the latter 136 tons by the end of 1943. In June 1943 Jardine Mining Co.,[2] which has not produced arsenic since 1936, contracted with the Metals Reserve Co. to furnish 5,000 tons of refined arsenic in 1944–45 from a new recovery plant. In December 1943 the Ferro Enamel Supply Co. (agent for Metals Reserve Co.), Cleveland, Ohio, contracted to deliver to E. I. du Pont de Nemours & Co., Inc., approximately 4,125 tons of calcium arsenate to be derived from treatment of cobalt-nickel speiss imported from Burma before the Japanese invasion.

White arsenic produced and sold by producers in the United States, 1939–43

Year	Crude			Refined			Total		
	Production (short tons) [1] [2]	Sales		Production (short tons)	Sales		Production (short tons)	Sales	
		Short tons	Value [3]		Short tons	Value [3]		Short tons	Value [3]

[1] Excludes crude consumed in making refined.
[2] Compounds made directly from ores, flue dust, and speiss contained white arsenic as follows: 1942, 290 tons; 1943, 172 tons.
[3] Partly estimated.
[4] Bureau of Mines not at liberty to publish.

FOREIGN TRADE [3]

Imports of white arsenic in 1943 were about the same as in 1942. The duty-free status was bound in the Reciprocal Trade Agreement with Mexico effective January 30, 1943. White arsenic exports, the greatest since 1939, went largely to United Kingdom, Canada, and U. S. S. R.

[1] Arsenic trioxide (As_2O_3) content; not strictly comparable with earlier years.
[2] According to the U. S. Department of Agriculture there have been no imports of london purple since 1936.
[3] As reported to Bureau of Mines by the producers, 1939–42; 1943: As reported by the U. S. Department of Commerce.
[4] Dealers exported an additional 1,077,244 pounds.
[5] Not separately classified.
[6] Figures cover July to December; not separately classified before July 1.

CONSUMPTION AND USES

Consumption of white arsenic in the United States increased 23 percent in 1943 compared with 1942 and established a new record.

Insects cause an annual loss of about 10 percent of all food and fiber crops, so their control is most significant. Calcium arsenate combats the boll weevil, tomato fruitworm, and other insects, and lead arsenate is effective against insects attacking fruits, flowers, and shrubs.[4] Production of calcium arsenate, 100 percent $Ca_3(AsO_4)_2$, was 34,932 short tons in 1943 compared with 38,898 tons in 1942; and production of lead arsenate (acid and basic) was 36,978 tons in 1943 compared with 31,789 tons in 1942, according to the United

States Department of Commerce. Insecticidal use of iron arsenate was described.[5]

The glass industry was greatly inconvenienced by its reduced share of arsenic, and it turned to such substitutes as antimony, sodium sulfate, and cerium.[6] Creosote and zinc chloride are the most important wood preservatives, but in addition 654 short tons of Wolman salts (25 percent sodium arsenate) and 120 tons of zinc meta-arsenate were used in 1942, according to the United States Forest Service. Arsenic acid is used in the manufacture of khaki dyes. Sodium arsenite is a poison bait—not recommended, however, for combatting Mormon crickets (grasshoppers).[7] Lead-base alloys containing up to 3 percent As substitute for tin-base babbitt and solder. About 3 to 10 pounds of white arsenic are consumed for each million cubic feet of industrial gas purified by the Thylox method.[8] Manufacturers and distributors of antisyphilitic drugs sold 30 million doses in 1943 compared with 33 million in 1942 and 18 million in 1941, according to the United States Public Health Service. Production of these drugs—neoarsphenamine, acetarsone, carbarsone, tryparsamide, arsenoxides (mapharsen, clorarsen, and phenylarsine), and sulfarsphenamine—totaled 83,026 pounds in 1943 compared with 66,753 pounds in 1942, according to the War Production Board.

White arsenic consumed in the United States, 1941–43, by uses

Use	1941		1942 [1]		1943 [1]	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total

[2] Includes wall board.
[3] Included under "Other."
[4] Gas purification, pharmaceuticals, cattle dip, paint, and other uses.

PRICES

White arsenic continued to be quoted at 4 cents a pound throughout 1943, according to Oil, Paint and Drug Reporter. The Bureau of Mines is not at liberty to publish the average value of producers' shipments. The base price of lead arsenate in carlots was set at 11–11½ cents a pound by the Office of Price Administration February 8, 1943 (Maximum Price Regulation 315). An amendment effective April 6 fixed the base ceiling price of other insecticides as follows (cents per pound in carlots): Calcium arsenate, 7–7½ cents; paris green, 20–25 cents; and london purple, 7–8 cents.

STOCKS

Stocks of white arsenic held by producers declined heavily in 1941–43 to help meet increased consumption.

Year-end stocks of arsenic compounds in the United States, 1939–43, in short tons

Year	White arsenic			Calcium arsenate [1] (producers)	Lead arsenate [2] (producers)
	Producers	Government	Total		
1939	5,505	----------	5,505	(3)	(3)
1940	6,944	----------	6,944	(3)	(3)
1941	4,518	----------	4,518	1,786	5,108
1942	2,187	2,693	4,880	2,584	2,223
1943	1,138	1,018	2,156	4,757	4,020

[1] Basis, 100 percent $Ca_3(AsO_4)_2$. From U. S. Department of Commerce.
[2] Acid and basic. From U. S. Department of Commerce.
[3] Comparable data not available. Suppliers held 12,500 tons of calcium arsenate and 5,000 tons of lead arsenate at end of 1940 compared with 2,650 and 5,625 tons, respectively, at end of 1941, according to the Agricultural Insecticide and Fungicide Association.

WORLD ASPECTS

World production of white arsenic in recent years, insofar as data are available, is shown in the accompanying table.

World production of white arsenic, 1936–43, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1936	1937	1938	1939	1940	1941	1942	1943
Australia:

[1] Arsenic is also believed to be produced in Czechoslovakia, Iran, Turkey, and U. S. S. R. Production figures are not available for these countries.
[2] Data not available; in 1936 to 1940, inclusive, estimate included in total.
[3] Estimate.
[4] January to June, inclusive.
[5] August to December, inclusive.
[6] Arsenic content of ores mined was as follows—1936: 23,312 tons; 1937: 20,954 tons; 1938: 21,480 tons; data not available for later years.

Brazil.—Of 477 metric tons of white arsenic output in the first half of 1943, St. John d'el Rey Mining Co. produced 386 tons; Cia. Minas da Passagem, 83 tons; and Cia. Brasileria de Mineracao S/A, 8 tons. Sales quotas and prices of white arsenic required authorization of the Chemical and Pharmaceutical Products Control after late 1943.

Canada.—Refined arsenic was produced by Deloro Smelting & Refining Co., Ltd., Deloro, Ontario, and Beattie Gold Mines, Ltd., Duparquet, Quebec, in 1943. Crude arsenic from the Beattie mine and O'Brien Gold Mines, Ltd., Cadillac Township, Quebec, was treated at Deloro. The main pillar in the glory hole of the Beattie mine collapsed June 16, 1943; consequently the mill was inoperative until December. During the shut-down period a plant for refining crude arsenic was installed.[9] Arsenical gold concentrates are shipped from British Columbia mines to the Tacoma (Wash.) smelter of the American Smelting & Refining Co. The contract of Wampum Gold Mines, Ltd., with the Metals Reserve Co., United States Government agency, lapsed.

Chile.—Native arsenic ore containing about 75 percent As and 60 ounces of silver per metric ton was offered for shipment.

Kenya.—Enough arsenical pyrite reserves have been proved by Messrs. Macalder Mines, Ltd., South Kavirondo, to supply the Colony cattle-dip and locust-poison requirements.[10]

Mexico.—White arsenic is produced by the American Smelting & Refining Co., San Luis Potosí, and by the American Metal Co., Ltd., Torreón.

Peru.—The Cerro de Pasco Copper Corporation began production of crude arsenic in June 1943, but there was little output in the third quarter because of difficulty in obtaining satisfactory containers. Steady production got under way in the fourth quarter, but by the end of the year only 93 metric tons had been delivered to Metals Reserve Co., the United States Government agency, on a contract calling for 800 tons monthly in 1943–44. Construction of a plant near Lima to produce copper arsenate for antimalarial use was begun in 1943.

Portugal.—British-owned companies exported 135 metric tons of refined arsenic from the Pintor mine and 30 tons of crude arsenic from the Panasqueira mine to United Kingdom in 1942.[11]

Southern Rhodesia.—Refined arsenic is produced at the Champion mine, Gwanda, and from Que Que Customs Roasting plant gold-bearing residues at Rodia Siding, Salisbury.[12] Arsenic has been excluded from excess profits tax to assist expansion.

Spain.—Several manufacturers of arsenicals plan to expand output.[13]

Sweden.—Arsenic is recovered from Boliden ores in such quantities as to make Sweden the world's largest producer. White arsenic now stored in concrete silos in that country is believed to exceed 300,000 tons.

Union of South Africa.—Shortage of arsenic for sheep and cattle dips has led to consideration of pyridines and other coal-tar compounds as a substitute.[14]

United Kingdom.—A plan for official approval of proprietary insecticides was placed in effect October 1942.[15] The price of refined white arsenic in 20-ton lots was raised from £40 to £59 per long ton in October 1943, according to Metal Bulletin. Arsenic metal continued to be quoted at £375 per ton.

BISMUTH

By ALLAN F. MATTHEWS

SUMMARY OUTLINE

	Page		Page
General statement	760	Stocks	762
Production	760	Prices	763
Foreign trade	760	World aspects	763
Consumption and uses	761		

GENERAL STATEMENT

Bismuth production in the United States in 1943 was little more than half that in 1942, but large imports and restricted consumption balanced supply and demand so as to obviate inventory withdrawals. Allocation control was instituted by the War Production Board over metallic bismuth February 1, 1943 (Order M-276), and over bismuth chemicals April 1, 1943 (Order M-295).

PRODUCTION

Bismuth metal production in the United States receded 44 percent in 1943 from the record high of 1942. The output, however, compared favorably with pre-war levels. Larger production in 1940-42 resulted in part from the cleaning up of residues accumulated over a period of years. The Bureau of Mines is not at liberty to publish data showing the domestic production of bismuth.

Three primary producers recover byproduct bismuth principally from domestic and imported lead and copper ores and from Mexican bismuth-lead bullion bars. The American Smelting & Refining Co. produces bismuth-lead alloys at its Selby (Calif.), Perth Amboy (N. J.), and Monterrey (Mexico) plants for refinement at Omaha, Nebr. From Montana copper and Utah lead ores the Anaconda Copper Mining Co., at Tooele, Utah, produces bismuth-lead bullion, which is refined by its subsidiary, International Smelting & Refining Co., East Chicago, Ind. The United States Smelting, Refining & Mining Co. ships bismuth-lead bullion from Midvale, Utah, for refinement at East Chicago, Ind., by its subsidiary, U. S. S. Lead Refinery, Inc. The principal importer and consumer is the Cerro de Pasco Copper Corporation, New York, which refines large quantities of bismuth in Peru.

FOREIGN TRADE[1]

Imports.—Bismuth ore imports in 1943 comprised 68,600 pounds (36.3 percent Bi) from Bolivia, 34,200 pounds (46.8 percent Bi) from Argentina, 29,800 pounds (12 percent Bi) from Mexico, and 6,000 pounds (72 percent Bi) from Brazil, according to the Foreign Economic Administration. The entire Mexican bismuth output (see world table at end of this chapter) is imported in the form of bismuth-lead bars (plus a small quantity of ore) for refining in the United States. All entries of refined metallic bismuth in 1939–43 were from Peru. There were no "imports for consumption" of the metal in 1942, and "general imports" of 222,684 pounds were reexported.

---

[1] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the United States Department of Commerce.

Bismuth imported for consumption in the United States, 1939–43

Year	Bismuth ore [1]			Refined metallic bismuth		Bismuth compounds and mixtures	
	Pounds		Value	Pounds	Value	Pounds	Value
	Gross weight	Bi content					
1939	(1)	(1)	(1)	182,832	$154,339	297	$649
1940	(1)	(1)	(1)	123,880	118,260	4	31
1941	(1)	(1)	(1)	223,477	223,463	41	744
1942	(1)	(1)	(1)	----------	----------	7	22
1943	138,600	48,800	$52,400	[2] 430,874	[2] 397,676	13	53

[1] Figures from Foreign Economic Administration. Those for 1939–42 are not available but are believed to be negligible.

[2] An additional 71,236 pounds (valued at $43,498) reported by the United States Department of Commerce as "bismuth" is ore and is covered by that category in this table.

Exports.—Exports of bismuth metal were 929 pounds in 1943 compared with 1,192 pounds in 1942 and went principally to Mexico and Argentina. Exports of bismuth alloys were 15,280 pounds in 1943 compared with 13,635 pounds in 1942; all were shipped to Canada.

Bismuth exported from the United States, 1941–43, by classes

Class	1941 (September-December) [1]		1942		1943	
	Pounds	Value	Pounds	Value	Pounds	Value
Matte	[1] 4,708	[1] $3,250	11,495	$6,387	10	$20
Metal and alloys	[1] 433,652	[1] 441,721	14,827	10,254	16,209	10,745
Compounds and mixtures:						
Carbonate	20,732	34,143	70,356	91,674	23,546	38,395

Sulfate	----------	----------	30	45	----------	----------
Other	4,854	8,897	25,129	36,651	5,936	12,510

[1] Figures for matte and for metal and alloys in 1941 cover July to December, inclusive. Earlier data are not available.

CONSUMPTION AND USES

Bismuth consumption in the United States was approximately 2,000,000 pounds in 1943 compared with an apparent consumption of 2,500,000 pounds in 1942, some 1,000,000 to 1,400,000 pounds annually in 1936–41, and 300,000 pounds annually during World War I.

Pharmaceuticals contained 49 percent of the bismuth consumed in 1943 compared with 85 to 90 percent in 1939. Such compounds are manufactured in about the same quantities as formerly, but the increased consumption of bismuth has been predominantly in metallurgical applications. Bismuth pharmaceuticals are used primarily in indigestion remedies but also in antisyphilitic drugs and cosmetic powder. As a conservation measure, the consumption in cosmetics was reduced in 1943. The use of thiobismol (sodium bismuth thioglycolate) with quinine has been recommended for malaria treatment.[2]

Bismuth alloys melt at low temperatures, and their volume expands or remains constant upon solidification from melts. These properties make alloys of bismuth (43–55 percent Bi) with lead, tin, and cadmium useful for pattern metal, assembly and checking fixtures, die and punch mounts, and filler for bending thin-walled tubing, particularly in the aircraft industry. Most of the tube bending, however, is now accomplished on machines by methods not utilizing bismuth filler. Bismuth solder (14 percent or more Bi) is an alternative of crimping for armor-piercing shells. Other bismuth solders[3] were used as a substitute for tin solders until tin became less critical than bismuth. Low-melting bismuth alloys serve as fuses in fire detectors, sprinklers, and gas containers and as coatings for selenium rectifiers.

Bismuth consumed in the United States, 1941–43, by uses

Use	1941 [1] (percent of total)	1942 [1] (percent of total)	1943 [2]	
			Pounds	Percent of total
Pharmaceuticals: Medicines and cosmetics	60	45	985,544	49
Pattern metal, mounts, and tube bending	15	15	652,558	33
Solders and bearings	10	31	[3] 237,212	12
Miscellaneous	15	9	[4] 129,077	6
Total consumption	100	100	2,004,391	100

[1] Estimated from producers' and importers' shipments.
[2] From War Production Board.
[3] Includes 208,632 pounds in ammunition solders; most of remainder in tin-saving solders.
[4] Includes 40,889 pounds in fuse alloys and 31,912 pounds in rectifier coatings.

STOCKS

Producers, distributors, and consumers reduced their bismuth stocks 70 percent in 1943, largely as a result of shipments to the Government stock pile. Striving toward the objective set in July 1943 of a 590,000-pound increment for the year, the Government-owned Metals Reserve Co. between January 1 and December 31, 1943, increased its stock pile of metallic bismuth from 352,701 to 832,697 pounds—all refined in the United States but including 529,922 pounds imported from Mexico in bismuth-lead bullion. During 1943 the Metals Reserve Co. also acquired 129,192 pounds of foreign bismuth ore, of which 28,592 pounds were resold before the year's close.

[3] Phillips, Albert J., Bismuth Solders: Metal Ind. (London), vol. 62, No. 10, March 5, 1943, pp. 150–151.

PRICES

Metallic bismuth continued to be quoted throughout 1943 at $1.25 per pound, ton lots, according to E&MJ Metal and Mineral Markets. Base prices of bismuth compounds, likewise unchanged, were listed by Oil, Paint and Drug Reporter as follows, per pound:

Chloride	$2.85	Oxychloride	$3.10	Subnitrate	$1.20
Citrate	2.75	Subbenzoate	3.40	Subsalicylate	2.50
Citrate, ammonia	3.40	Subcarbonate	1.50	Sulfocarbolate	3.65
Hydroxide	3.35	Subgallate	1.40	Trioxide	3.65
Nitrate	1.30	Subiodide	4.13		

WORLD ASPECTS

World production of bismuth approximated 1,400,000 kilograms (3,000,000 pounds) in 1943. The principal producers were the United States, Peru, Canada, and Mexico.

World production of bismuth, 1938–43, by countries, in kilograms[1]

[Compiled by B. B. Waldbauer]

Country[1]	1938	1939	1940	1941	1942	1943
Argentina		[2] 2,860	4,880	10,040	(3)	[4] 20,900
Australia (in ore)[5]	4,600	2,200	2,800	2,200	4,800	6,800
Bolivia (in ore and bullion exported)[6]	17,194	12,653	18,700	22,604	8,896	12,419

In lead-bismuth alloy	13,178	52,430	56,314	178,138	16,913	
Spain (in ore)			41,830	(3)	(3)	(3)
Union of South Africa (in ore)	2,636	1,379	(3)	(3)	[7] 3,000	(3)
United States	(8)	(8)	(8)	(8)	(8)	(8)
World production (estimate)	1,000,000	1,300,000	1,400,000	1,400,000	1,700,000	1,400,000

[1] Bismuth is believed to be produced also in Brazil, Burma, China, France, Germany, Japan, Rumania, Sweden, Uganda, U. S. S. R., United Kingdom, and Yugoslavia. Production figures are not available for these countries, but estimates by author are included in total.

[2] In ore.

[3] Data not available. Estimate included in total.

[4] Content of ore exported to United States.

[5] Partly estimated. Excludes content of some bismuth-tungsten concentrates.

[6] Excludes bismuth content of tin concentrates exported.

[7] Estimated.

[8] Production included in total; Bureau of Mines not at liberty to publish figure.

Bolivia.—A surtax of 15 to 25 percent on bismuth exports was decreed May 6, 1942. Campagnie Aramayo de Mines en Bolivio and Fabulosa Consolidated Co. are the principal producers of bismuth ore in Bolivia, although a number of small operators are selling to Banco Minero de Bolivio. It would be possible for these companies plus Patino Mines & Enterprises Consolidated, Inc., to mine ore containing 275,000 kilograms (600,000 pounds) of bismuth annually for a few years, according to the United States Foreign Economic Administration.

Mexico.—Bismuth-lead bars and a little bismuth ore are shipped to the United States for refining. The ore exported in 1943 was from the Rey de Bismuto property, northeast of Culiacán, Sinaloa.

Peru.—According to the United States Foreign Economic Administration, four-fifths of Peruvian bismuth is from lead mines, principally the Colquijirca lead-silver mine, and one-fifth is from the San Gregorio silver-bismuth mine, which is expected to be exhausted in about a year. The ores are smelted at Oroya by the Cerro de Pasco Copper Corporation. Exports of refined bismuth in 1943 were 483 metric tons—258 to England and 225 to the United States; the latter includes 30 tons sunk by submarine attack in the Caribbean Sea in November.

MAGNESIUM

By John H. Weitz and M. E. Trought

SUMMARY OUTLINE

	Page		Page
Summary	765	Foreign trade	772
Salient statistics	765	War measures	772
Production	766	Technologic developments	773
Consumption	768	Post-war outlook	774
Prices	771	World production	775

SUMMARY

Production of primary magnesium in the United States in 1943—nearly four times that in 1942—exceeded demands of the war program and was so great that early in 1944 nearly 40 percent of total installed capacity was shut down. For the second straight year production exceeded the combined output in this country since the inception of the industry in 1915.

Salient statistics of the magnesium industry in the United States, 1939–43

	1939	1940	1941	1942	1943
Production of primary magnesium......short tons..	3,350	6,261	16,295	48,963	183,584
Quoted price per pound [1]..........cents..	27.0	27.0	22.5	22.5	20.5
Exports..........short tons..	2,100	859	[2] 1,549	[2] 4,045	35,631
World production (estimated)..........do....	34,100	49,500	85,500	154,500	296,600

[1] Lowest nominal price (New York) for primary metal ingot 99.8 percent pure, carlots.

[2] Magnesium metal in primary form.

Companies using electrolytic processes for producing magnesium supplied over 85 percent of total output and ferrosilicon and carbothermic processes the remaining 15 percent. Four new plants were put in operation during the year—including Dow Magnesium Co. at Marysville, Mich., Amco Magnesium Co. at Wingdale, N. Y., Electro Metallurgical Co. at Spokane, Wash., and Mathieson Alkali Works at Lake Charles, La.—and all primary metal plants were virtually completed during the year.

Primary magnesium shipped or used (sales) in 1943 totaled 170,267 tons compared with 47,420 tons in 1942. Apparent consumption totaled 155,547 tons (43,375 tons in 1942). By mid-1943 magnesium had been taken off the critical list by War Production Board, and by the end of the year stocks had been built up and supply considerably exceeded demand.

World magnesium output reached a new high mark in 1943, and estimates based upon incomplete statistical data indicate that United States far outstripped the rest of the world. Axis and Axis-dominated countries produced only about 28 percent of the total output, whereas the United Nations furnished 72 percent. Probabilities are that world production will not increase greatly in 1944.

PRODUCTION

Primary magnesium.—Domestic production of primary magnesium in 1943 totaled 183,584 short tons, a 275-percent increase over the 1942 output of 48,963 tons. Primary magnesium shipped or used (sales) totaled 170,267 tons, or 259 percent more than in 1942 (47,420 tons). Basic Magnesium, Inc., at Las Vegas, Nev., Dow Chemical Co. at Midland, Mich., and Freeport, Tex., Dow Magnesium Corporation at Velasco, Tex., and Marysville, Mich., Diamond Magnesium Co., at Painesville, Ohio, and International Minerals & Chemical Corporation at Austin, Tex., produced the bulk of the domestic output of primary metal in 1943—about 85 percent—and the remaining 15 percent was divided among Amco Magnesium Corporation, Wingdale, N. Y., Electro Metallurgical Corporation, Spokane, Wash., Ford Motor Co., Dearborn, Mich., Magnesium Reduction Co., Luckey, Ohio, Mathieson Alkali Works, Inc., Lake Charles, La., New England Lime Co., Canaan, Conn., and Permanente Metals Corporation at Manteca and Permanente, Calif.

Construction on all primary-magnesium-producing facilities was virtually completed during 1943, and all plants operated during the year. Metal was first produced at the Amco Magnesium Co. ferrosilicon-process plant at Wingdale, N Y., during March. Dow Magnesium Corporation poured the first metal at its gigantic 72,000,000-pound Marysville (Mich.) plant in April, and the Ludington magnesium chloride feed plant was in operation a few months thereafter. In May, first production was obtained from the ferrosilicon-process plant of Electro Metallurgical Corporation at Spokane, Wash. On June 7 the last primary magnesium plant to come into commercial production—the Mathieson Alkali Works, Inc., plant at Lake Charles, La.—began to produce metal from magnesium chloride in electrolytic cells of its own design.

The annual rate of production rose from about 125,000 tons in January 1943 to 182,000 tons in June and to 236,000 tons in December. This rapid climb in the rate of output during 1943 culminated in January 1944, when metal was produced at a record rate of 246,000 tons a year. From January to April 1944 the production rate declined steadily, to about 216,000 tons annually; cut-backs effected in the first half of 1944 assure that the decline will continue at least through August, when it is believed the annual production will have declined to approximately 180,000 tons a year. Thus it is likely that the high point of magnesium production has arrived and passed and that an output rate comparable to that in January (about 84 percent of rated total annual capacity) may not again be reached for at least a decade.

As early as mid-1943 it began to be apparent that there would be a surplus of magnesium over and above essential military requirements. Accordingly, the Dow plants, which had been producing considerably in excess of capacity, were curtailed slightly on a voluntary basis. However, not until March 1, 1944, were any substantial cut-backs effected at other plants. Between March 1 and June 1 the following plants had been ordered to cease production: Amco Magnesium Co. (ferrosilicon process); Ford Motor Co. (ferrosilicon process); Mathieson Alkali Works, Inc. (modified electrolytic process); and Permanente Metals Corporation (Manteca, ferrosilicon process). The following were curtailed: Basic Magnesium, Inc. (Magnesium Elektron electrolytic process), cut to 60 percent; Dow Magnesium Corporation (Marysville, Dow process), cut to 60 percent; Electro Metallurgical Corporation (ferrosilicon process), cut to 50 percent; and Dow Chemical Co. (Midland, Dow process), voluntarily cut to about 55 percent of rated capacity. Total shut-downs and curtailments through June 1 represented approximately 39 percent of total rated capacity. By types of process, cut-backs in rated capacity were approximately as follows: Ferrosilicon, 68 percent; electrolytic (excluding Basic Magnesium), 29 percent; M. E. L., 40 percent; carbothermic, no cut.

Three wildcat strikes during 1943 interrupted production of aviation engine parts at the Cleveland (Ohio) plant of American Magnesium Corporation. The strikers, affiliated with the United Mine, Mill and Smelter Workers, C. I. O., walked out on June 23 to try to force rotation of shifts, again on July 20 over bonuses, and the third time late in November against a system of visitor's passes. As the result of a union election, the Mine, Mill and Smelter Workers, C. I. O., ousted the incumbent A. F. L. organization at the Las Vegas plant of Basic Magnesium, Inc., by a close vote.

On March 13, 1944, the Senate Special Committee to Investigate the National Defense Program (Harry S. Truman, chairman) released its report on the magnesium situation in the United States.[1] This report summarizes the history of the magnesium industry in the country both before and during the war. Discussion of various processes, used and not used, and a detailed record of the "bungling and incompetence displayed in the promotion and construction of Basic Magnesium plant at Las Vegas, Nev.," take up much of the space in the report. The report recommended the removal of restrictions on magnesium in view of the large excess of producing capacity. The Committee also recommended that attention be given to new methods of fabrication and new civilian uses, to the end that magnesium will have a better chance to survive as a major industry in the post-war world.

Old and new companies that expanded or began to fabricate magnesium in 1943 through the Defense Plant Corporation included American Radiator & Standard Sanitary Corporation, Litchfield, Ill.—3,600,000 pounds of sand castings annually; Aluminum Co. of America, Garwood, N. J.—900,000 pounds annual expansion to die-casting works; Central Foundry, Inc., Anniston, Ala.—2,400,000 pounds of sand castings annually; Doehler Die Casting Co., Chicago, Ill.—1,000,000 pounds of die castings annually; The Hoover Co., North Canton, Ohio—500,000 pounds of die castings annually; Metal Mold Magnesium Corporation, Cedarburg, Wis.—600,000 pounds of die castings annually; Precision Castings Co., Syracuse, N. Y.—1,200,000 pounds of die castings annually; and Ruppert Die Casting Co., Kansas City, Mo.—300,000 pounds of die castings annually.

Secondary magnesium.—Recovery of secondary magnesium totaled 11,404 short tons (including secondary magnesium incorporated in primary magnesium ingot) in 1943 (6,238 tons in 1942) and required the consumption of 13,909 tons of magnesium scrap, which was almost entirely new scrap. Of the quantity of magnesium recovered, 11,009 tons were as ingot, and 327 tons went into castings, 34 into aluminum alloys, 1 into zinc alloys, and 33 into chemical reagents and metallurgical processes. Additional information on secondary magnesium will be found in the chapter on Secondary Metals—Nonferrous.

[1] Magnesium: Investigation of the National Defense Program, 78th Cong., 2d sess., Rept. 10, pt. 17, March 13, 1944.

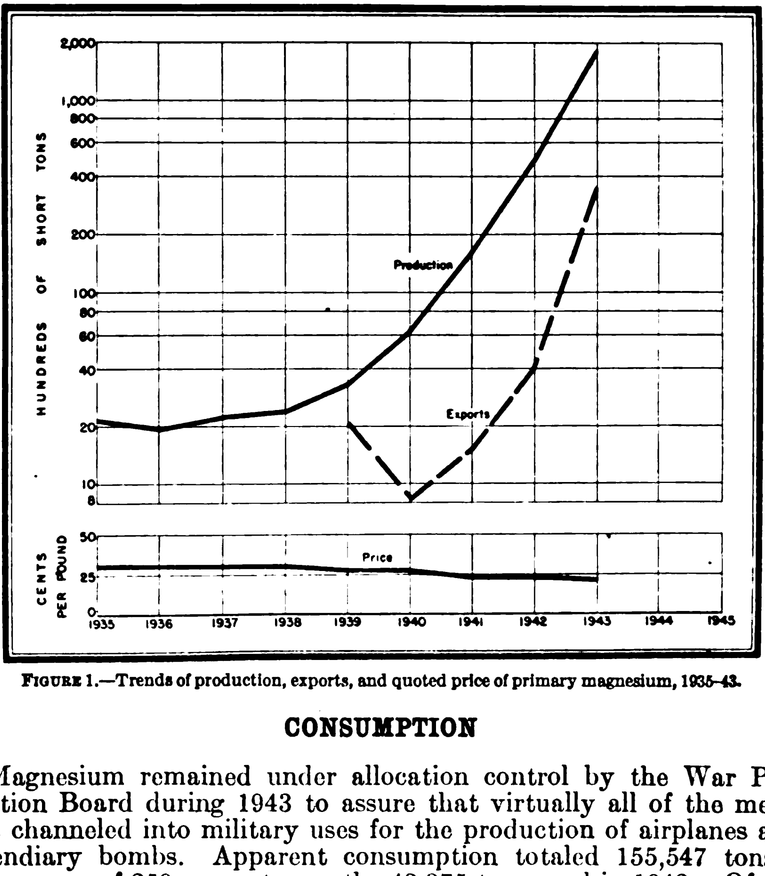

FIGURE 1.—Trends of production, exports, and quoted price of primary magnesium, 1935–43.

CONSUMPTION

Magnesium remained under allocation control by the War Production Board during 1943 to assure that virtually all of the metal was channeled into military uses for the production of airplanes and incendiary bombs. Apparent consumption totaled 155,547 tons—an increase of 259 percent over the 43,375 tons used in 1942. Of the primary magnesium shipped or used in 1943 (170,267 tons), approximately 64 percent was used in the manufacture of magnesium-base alloy structural products; 8 percent in other alloys, chiefly aluminum; 7 percent in powder; and 21 percent for export account (includes 20,911 tons of magnesium-base alloy).

No survey on the consumption of primary and secondary magnesium was conducted by the Bureau of Mines during 1943, and for this reason no data on actual consumption are available.

Production, sales, exports, and apparent consumption of primary magnesium in the United States, 1939–43, in short tons

Year	Production	Sales	Exports	Apparent consumption [1]
1939	3,350	5,325	2,100	3,225
1940	6,261	6,411	[2] 834	5,577
1941	16,295	15,528	1,549	13,979
1942	48,963	47,420	4,045	43,375
1943	183,584	170,267	[3] 14,720	155,547

[1] Does not consider fluctuations in consumers' stocks and metal derived from scrap. Withdrawals from producers' stocks totaled 1,975 tons in 1939; 150 tons in 1940; additions to producers' stocks totaled 767 tons in 1941; 1,543 tons in 1942; and 13,317 tons in 1943.

[2] Of the 859 tons of metal exported, 25 tons consisted of magnesium alloy.

[3] Of the 35,631 tons of metal exported, 20,911 tons consisted of magnesium alloy.

Magnesium products (other than ingot) manufactured in the United States and sold or used by the companies manufacturing the products, 1941–43

Product	1941		1942		1943

[1] Estimated.

[2] Not available.

Magnesium-base-alloy structural products manufactured and sold or used in the United States increased 200 percent over 1942. The manufacture of powder sold or used increased 234 percent. Of the structural products sold or used, sand castings comprised 43 percent, permanent mold castings 53 percent, die castings 2 percent, sheet 1 percent, and other structural products 1 percent. The estimated average value of sand castings manufactured in 1943 was $2.11 a pound, permanent mold castings $1.15, die castings $1.96, and all castings $1.59 a pound (compared with $1.87 in 1942).

Of the magnesium-alloy structural products sold or used the aircraft industry took 50 percent, incendiary bomb casings 50 percent, and other industries less than 1 percent. Of that going into the aircraft industry, 64 percent was for the manufacture of engines (including propellers), 23 percent for wheels, 7 percent for frames, and 6 percent for accessories. Sand, die, and permanent mold castings comprised 96 percent of all magnesium-alloy structural products sold for or used in aircraft.

Consumption of magnesium-base-alloy structural products in 1941–43, by uses, in short tons

	1941	1942	1943
Aircraft:			
Engine	3,972	[1] 11,815	21,903
Frame	679	1,319	2,546
Wheel	1,439	4,162	7,698
Accessories	443	648	1,885
Incendiary bomb casings	8	4,735	33,988
Other industries	297	109	352
Total	6,838	22,788	68,372

[1] Includes some alloy used in the manufacture of aircraft frame, wheel, and accessories.

Fabricators of magnesium structural products increased from 59 in 1942 to about 85 in 1943 and of powder from 19 to 20. By the end of 1943, more than 37 companies were producing sand castings, 13 permanent mold castings, 14 die castings, 3 extruded products, 3 forgings, and 16 powder. The largest producers of alloy structural products were:

Acme Metal Products, Los Angeles, Calif.
American Magnesium Corporation, Cleveland, Ohio.
American Radiator & Standard Sanitary Corporation, Louisville, Ky.
Armstrong Cork Co., Lancaster, Pa.
Austin Bridge Co., Dallas, Tex.
Bohn Aluminum & Brass Corporation, Detroit, Mich.
Chevrolet Grey Iron Foundry, Saginaw, Mich.
Dalmo Victor Co., San Francisco, Calif.
Dodge Chicago Plant of Chrysler Corporation, Chicago, Ill.
Doehler Die Casting Co., New York, N. Y.
Dow Chemical Co., Midland, Mich.
Eclipse Aviation Corporation, Bendix, N. J.
Ferro Enameling Co., Oakland, Calif.
Ford Motor Co., Dearborn, Mich.
Hills-McCanna Co., Chicago, Ill.
Howard Foundry Co., Chicago, Ill.
International Silver Co., Meriden, Conn.
Magnesium Products, Inc., Los Angeles, Calif.
Marshall Stove Co., Lewisburg, Tenn.
McWane Cast Iron Pipe Co., Birmingham, Ala.
Michigan Light Alloys Corporation, Grand Rapids, Mich.
Metal-Mold Magnesium Corporation, Cedarburg, Wis.
Monarch Aluminum Manufacturing Co., Cleveland, Ohio.
Stewart Die Casting Co., Chicago, Ill.
Vitreous Steel Products Co., Nappanee, Ind.
Wellman Bronze & Aluminum Foundry, Cleveland, Ohio.
Wright Aeronautical Corporation, Paterson, N. J.

Producers of powder included:

American Magnesium Corporation, Cleveland, Ohio.
California Fuel & Utilities, Inc., San Francisco, Calif.
Ferro Enamel Corporation, Cleveland, Ohio.
Imperial Paper & Color Corporation, Glens Falls, N. Y.
Magna Manufacturing Co., New York, N. Y.
Metals Disintegrating Co., Elizabeth, N. J.
National Fireworks, Inc., West Hanover, Mass.
National Magnesium Co., Elkton, Md.
New England Magnesium Co., Malden, Mass.
Pacific Coast Chemical Co., Aberdeen, Wash.
Pilgrim Ordnance Works, West Hanover, Mass.
Pulverizing Machinery Co., Roselle Park, N. J.
Reade Manufacturing Co., Inc., Lakehurst, N. J.

United States Magnesium Corporation, Pleasant Valley, N. Y.
United Wallpaper Factories, Inc., Chicago, Ill.
Universal Match Corporation, St. Louis, Mo.

PRICES

At the request of the Office of Price Administration, Dow Chemical Co. reduced its base price of standard four-notch magnesium ingot from 22.5 to 20.5 cents a pound on January 1, 1943. Effective February 1 the Office of Price Administration, in Maximum Price Regulation 314, established 20.5 cents a pound as the maximum price per pound for standard four-notch ingot, except for sales to the Metals Reserve Co. Magnesium-alloy ingot maximum prices included in the above regulation were: Incendiary bomb alloy, 23.4 cents; 50–50 magnesium-aluminum alloy, 23.75 cents; A. S. T. M. B 80–41 T 11 and A. S. T. M. B 94–41 T 13, 25 cents; and all other alloys, 23 cents. By Amendment 1 to Maximum Price Regulation 314, manufacturers of primary magnesium alloys, except those who also produce the metal, were allowed to carry out contracts with Government agencies at prices prevailing before February 1 to avoid loss on inventories of the metal and its alloys they had on hand at that date. On May 26 in Amendment 2, sellers of all magnesium or magnesium-alloy ingot manufactured in nonstandard shapes and sizes were permitted to add a premium of 1 cent a pound to applicable maximum base prices provided that the purchaser specifically requested the particular shape or size. On August 4 sellers of the above-mentioned nonstandard shapes or sizes that could not be produced for the 1-cent-a-pound premium were authorized in Amendment 3 to submit proposed prices to the Office of Price Administration for approval.

On December 29, 1943, Amendment 4 added a maximum price of 23.5 cents a pound for "selected magnesium crystals, crowns, and muffs" which included all packing, preparation, and handling charges. Also added to the regulation was a stipulation that a charge of one-half cent a pound may be added to the applicable maximum base price of magnesium or magnesium-alloy ingot, other than selected crystals, crowns, and muffs, for paper packaging or shipping in wire-bound bundles. On March 11, 1944, by Amendment 5, the Office of Price Administration placed magnesium powder under Maximum Price Regulation 314, and ceiling prices remained at the highest prices charged by individual sellers during March 1942.

Magnesium scrap and remelt ingot, controlled under the General Maximum Price Regulation during 1942, were placed under specific maximum prices by Maximum Price Regulation 302, effective January 20, 1943. For scrap, lots of less than 1,500 pounds, the prices were set as follows: Segregated plant scrap—all exempt except borings and turnings—8 cents a pound; contaminated plant scrap, 11 cents for grade 1 solids and 9 cents for grade 2 solids, and 7 and 5 cents, respectively, for grades 1 and 2 borings and turnings; obsolete scrap, uncontaminated, 11 cents, and contaminated, 9 cents. For lots of more than 1,500 pounds 1 cent may be added to the maximum price in each category. Actual costs of transportation may also be charged. Prices for remelt magnesium ingot were set at 21.5 cents a pound for class A, 18.5 cents for class B, and 16 cents for class C, Premiums may be added to these prices for transportation charges, when quantities are less than 20,000 pounds, as follows: One-fourth cent from 10,000 to 20,000 pounds, one-half cent from 1,000 to 10,000 pounds, and 1 cent for less than 1,000 pounds. Amendment 1 to this regulation, effective July 1, allows payment of a service charge to scrap dealers for loading scrap into railroad cars and exempts remelt magnesium ingot containing 99 percent or more magnesium from price control.

FOREIGN TRADE[3]

Imports of magnesium in all forms in 1943, all of which came from Canada, totaled 189 pounds valued at $86 and consisted of 28 pounds of metal and scrap; 135 pounds classed as sheets, tubing, ribbon, etc.; 8 pounds of alloys; and 18 pounds of powder.

Exports of magnesium from the United States, 1942–43

	1942		1943	
	Short tons	Value	Short tons	Value
Magnesium metal in primary form	4,045	$1,945,164	[1] 35,631	$16,272,607
Magnesium metal in other forms	149	99,517	2,673	1,475,303
Magnesium powder	22	66,038	2,125	1,207,429

[1] Includes 20,911 tons of magnesium-base alloy.

Exports of metal in primary form included 31,894 tons which went to the United Kingdom, 3,623 to the U. S. S. R., 70 to Canada, 40 to Mexico, and 4 tons to Turkey, Newfoundland, Labrador, and Haiti. Of the magnesium metal in other forms, 2,505 tons were destined to the United Kingdom, 134 to Canada, 11 to Australia, 20 to Mexico, and 3 to Panama Canal, Brazil, Newfoundland and Labrador, Chile, Uruguay, Argentina, China, and the Union of South Africa. Magnesium powder exported during the year included 2,088 tons destined to the United Kingdom, 16 for Australia, 9 each for Canada and the Union of South Africa, and 3 for China, Mexico, Peru and Brazil.

In 1943 exports of magnesium metal in primary form were equivalent to about 19 percent of the total domestic production compared with 8 percent in 1942.

WAR MEASURES

Magnesium General Preference Order M-2-b, now in force, was originally issued on November 14, 1941, to conserve and direct the distribution of magnesium. On December 31, 1942, the order was extended indefinitely and amended by omission of all references to preference ratings since the supply of magnesium and magnesium products is allocated directly to users. By an amendment to the order on January 13, 1944, the War Production Board simplified procedures governing the allocation and use of magnesium and magnesium products and the segregation and disposal of scrap. The amendment permits foundries to accept the return of rejected or spoiled castings of their own manufacture without obtaining prior approval of the War Production Board; they will no longer be required to sell such castings to a producer or approved smelter. The amendment also redefines "magnesium scrap" to exclude sawings, grindings, sweepings, and similar fines and also dross and sludge containing less than 20 percent magnesium by weight. Plants generating less than 1,500 pounds of scrap a month are freed from the requirement that they segregate their scrap, but those generating more than this amount must segregate it in accordance with A. S. T. M. alloy designations to facilitate its hauling and reprocessing. By Directive 34, the War Production Board on January 17, 1944, delegated authority to grant specific authorizations to deliver magnesium products going into aircraft and aircraft equipment to the Aircraft Scheduling Unit of the Aircraft Resources Control Board.

---

[3] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

TECHNOLOGIC DEVELOPMENTS

Improvements in magnesium-fabricating techniques have paced expanding production. Among the more important of these has been an improved stability of alloys, made possible largely through more careful control of their purity. For instance, it has been found that if the iron content is controlled to very close limits, corrosion resistance is materially increased.[4] A new method devised for satisfactorily arc-welding magnesium sheet or other products utilizes a tungsten electrode and a filler rod of the alloy being welded, the arc being maintained in a neutral atmosphere such as that provided by helium gas.[5] Wartime needs have increased knowledge on plastic working of magnesium alloy sheet,[6] sand casting of magnesium alloys,[7] and the technology of production of magnesium-base alloys.[8] Surface protection of magnesium and its alloys is essential because the resistance of the metal to corrosion is lowered in climates of high humidity and temperature, and there has therefore been considerable research on coating methods.[9] Knight [10] reviewed the latest methods for the prevention and control of magnesium fires and concluded that G–1 powder, "a mixture of graphite and complex materials," was probably the most efficient medium for extinguishing magnesium fires.

The application of a process of "mechanical ingoting" of magnesium and aluminum borings and turnings has recently been devised by which this type of scrap, if segregated at the point of origin and kept clean, can be made into ingot suitable for melting as well as deoxidation and alloying.[11] Solid ingots of practically 100-percent density are said to result from this method, with a metal recovery of virtually 100 percent.

A number of patents relating to magnesium were granted during 1943. Among those relating to the production of metallic magnesium from its ores are the following: The Pidgeon ferrosilicon reduction process (United States Patent 2,330,143); and at least five variations on the carbothermal reduction process wherein magnesium is released from its oxide as a vapor and must be shock-cooled to prevent the reversible reaction from taking place—the method of cooling being the main variant in the patents—(United States Patents 2,308,418, 2,323,597, 2,328,202, 2,330,724, and 2,334,451). At least 10 different patents relating to coating and protecting magnesium and magnesium alloy surfaces were granted. Agents proposed for producing corrosion-resistant surfaces include aqueous solutions of fluorides; solutions of chromic acid; solutions of basic aluminum nitrate and at least one alkali chromate with a suitable wetting agent; and an arsenic compound dissolved in water. Other patents granted during the year include a number relating to recovery of magnesium scrap and many covering new alloy combinations of magnesium.

POST-WAR OUTLOOK

With a domestic capacity to manufacture magnesium totaling 293,000 tons annually by the middle of 1944—90 times the pre-war (1939) capacity—it is apparent immediately that peacetime uses must be greatly expanded to consume any substantial percentage of available metal. All magnesium is now being used for war purposes—planes, incendiaries, and other battle equipment—and for essential civilian and war-supporting industries. For the most part these uses will virtually cease when hostilities terminate, and new and expanded peacetime uses must be found unless a large segment of the production industry as well as many fabricating plants are to be closed for a long period of time.

Magnesium has proved its worth in aircraft construction, particularly in landing gear, fuel tanks, instrument panels, and certain engine parts as magnesium base-alloy sheet and castings. Wartime experience and advances have shown that the metal is easily machined and that its alloys with aluminum, zinc, and copper are not only very light but high in strength. It is conceivable that by using alloying, casting, and forming techniques learned during the war manufacturers of motor cars and other transportation facilities will find uses for the metal in their post-war products. Excellent machinability and damping characteristics, as well as the nonsparking and nonmagnetic properties of magnesium, are arguments in favor of wider peacetime adoption of the metal. Certain disadvantages, limiting the use of the metal in some fields, should be borne in mind when post-war plans are being made. These include (1) a lower modulus of elasticity than steel and aluminum, (2) higher thermal expansion, (3) lower corrosion resistance, (4) greater reduction in strength with temperatures over 300° C. than steel and aluminum, and (5) susceptibility to the effect of concentrated stresses.

Cost of the metal is perhaps one of the most important considerations in evaluating post-war possibilities for its use. The present cost—20.5 cents a pound—is higher than that of both aluminum and copper, but when taken volume for volume it is less expensive. Further reductions in cost will undoubtedly be forthcoming after the war through advances in technology and reduced operating costs, and these reductions will have a pronounced effect on the promotion of large-scale use of the metal. Part of the price question hinges on the payment the Government will demand for productive facilities, of which it owns the preponderant share. The construction costs of the Government-owned facilities, built with public funds under the stress of war, will seem exorbitant by peacetime standards.

One fact that will loom important in the long-term outlook for magnesium is its abundance in the earth's crust, ranking third among the metals. Commercial sources of the metal include sea water, a virtually inexhaustible resource; dolomite, which occurs in large sedimentary deposits throughout the world; underground brines; and magnesite. For practical purposes, reserves of all of these except magnesite are limitless. Other sources that may be used in the future include olivine and serpentine—silicates of magnesium—which are found in great quantities in various parts of the world.

WORLD PRODUCTION

World production of magnesium in 1943 reached another all-time high mark of more than 269,000 metric tons—92 percent more than the previous record of 140,000 tons set in 1942 and more than eight times the 1939 output. The statistical background for the production figures of nations other than the United States, Canada, and the United Kingdom is very weak, but upon the basis of estimates it is thought that about 28 percent of the output was under Axis control and 72 percent under control of the United Nations. Production in 1944 will not greatly exceed that of 1943, inasmuch as all the major expansion programs of the various nations are thought to be virtually complete.

Estimated world production of magnesium, 1939–43, by countries, in metric tons

Country	1939	1940	1941	1942	1943
Australia	....	....	200	430	800
Canada	....	....	[1] 5	[1] 367	[1] 3,243
France	2,500	2,000	3,000	3,000	3,000
Germany	16,500	25,000	35,000	50,000	50,000
Italy	300	500	2,500	5,000	5,000

United States	[1] 3,039	[1] 5,680	[1] 14,782	[1] 44,418	[1] 166,544
Total	30,900	44,900	77,600	140,200	269,100

[1] Actual production.

Canada.—According to the Dominion Bureau of Mines, the output of magnesium in Canada has increased from 5 metric tons in 1941 to 3,243 tons in 1943. The Ministry of Munitions and Supply stated in June 1943 that the output of Dominion Magnesium, Ltd., at Haley's Station near Renfrew, Ontario, was meeting all Canadian requirements and allowing some margin for exports. Production of metal, using nearby dolomite as the raw material for the Pidgeon process, is stated to have reached the rated capacity of 10 tons a day. Latest reports of the cost per pound of the metal produced in this ferrosilicon plant are that in March 1943 costs had been lowered to 39.7 cents a pound. The Minister of Munitions and Supply stated that it was hoped costs could be brought down to the level of the electrolytic process.

Dominion Magnesium, Ltd., has begun the production of alloy munition castings, presumably incendiary bomb casings, at Haley's Station.

Early in 1944 it was announced that magnesium, the entire output of which was formerly used for war requirements and for export, is now permitted to be sold on the free market.

Japan.—Two new companies were formed during the year—Nippon Kazei-Kyogo by the Mitsubishi Co. in Kwantung Leased Territory of China, at a capitalization of 200,000,000 yuan, which is planned to begin operations in the fall of 1944, and the Imperial Magnesium Co. in Japan proper, through the merger of the Toa Light Metals Co. and the Okura Magnesium Mining Co., with a capitalization of 20,000,000 yen.

Norway.—In July 1943 the newly completed magnesium plant at Heroya was completely destroyed during an American air raid.

Sweden.—All restrictions on sales of magnesium and its alloys, semifinished products, magnesium ashes, scrap, and waste were abolished on March 1, 1944.

United Kingdom.—Four companies are operating magnesium plants in Great Britain, and each uses a different process. Since 1935 a subsidiary of Murex, Ltd., has used calcium carbide as a reducing agent. A mixture of carbide and magnesia is heated in vertical gas-fired retorts of heat-resisting steel under a vacuum. Calcined dolomite may be used to produce the metal, which is recovered in crystal form, but the yield is reduced by the amount of lime in the dolomite.

International Alloys, Ltd., operates a plant utilizing sea-water magnesia, which is finely ground and briquetted with aluminum or an alloy containing aluminum. The briquets are placed in electric resistance furnaces and heated to 1,100° to 1,250° C. under pressure of less than 4 mm. The magnesium is then distilled off and collected as high-purity crystals in the cooler part of the retort. This process is similar in nature to the above calcium carbide process and to the Pidgeon or ferrosilicon process.

In 1935 Magnesium Electron, Ltd., was formed to operate an electrolytic process, patent rights for which were purchased from I. G. Farbenindustrie, A. G. The method is similar to that used by Basic Magnesium, Inc., near Las Vegas, Nev., which was patterned after the British plant although on a tenfold scale. The capacity of the British plant at Clifton Junction near Manchester is thought to be about 5,000 tons annually, and the process is considered the cheapest now operating in the Empire.

The Hansgirg process of carbothermal reduction of magnesia is used by Magnesium Metal Corporation, Ltd. Hydrogen is used in this plant, as at Radenthein, Austria, for shock-cooling the vaporized metal, but otherwise the process is quite similar to that used by Permanente Metals Corporation in California.

Reports early in 1944 indicate that one of the British plants has been closed and that two others may be curtailed.

SUMMARY

Although antimony continued under Government control throughout 1943, the largest supply on record not only permitted use restrictions to be relaxed, with a resultant gain in consumption, but enabled stocks to be increased. The new supply—almost entirely imported—came largely from Bolivia and Mexico in nearly equal amounts and was augmented by a marked advance in domestic production. By the end of the year the situation was so easy that antimony was removed from allocation control, effective January 1, 1944.

Domestic production of antimony ore increased 140 percent over 1942, but the metal content advanced only 91 percent—an indicated drop in the average grade from 42 percent in 1942 to 34 percent in 1943. The number of antimony mines in operation was about one-half that in 1942, the large gain resulting from expanded operations at one property which supplied over three-quarters of the output. The antimony content of antimonial lead produced from all classes of foreign and domestic ore declined, the drop being greater than a substantial gain in the recovery from scrap. Primary antimony available for consumption was 52 percent greater than in 1942. Actual consumption was less than the supply, and although industry stocks showed a 14-percent decrease, total inventories, including those held by the Government, gained 45 percent.

The price of antimony metal in less than carlots was quoted at 16.05 cents a pound in New York until June 3, when the benefits of a lower freight rate were passed on to consumers by reduction of the selling price to 15.84 cents a pound. The average price of 15.92 cents in 1943 compares with 15.55 cents in 1942 and 14.00 cents in 1941 and 1940. The prices for antimony ore and concentrates remained unchanged throughout 1943. The 50- to 55-percent ores were quoted at $2.10 to $2.20 per short-ton unit of contained antimony at New York.

Figure 1 shows trends in world production from 1910 to 1938 and United States imports and prices from 1910 to 1943.

POST-WAR OUTLOOK

Domestic production of primary antimony has been stimulated by war conditions, but most of the gains were made at mines operated chiefly for other metals. The increase at the Yellow Pine mine in Idaho has been notable, but operations at this property are predicated largely on the demand for tungsten, the more valuable constituent of the ore mined. Antimony in the United States has always been largely produced as a byproduct, and present indications are that it will remain so in the future. Primary antimony requirements will therefore continue to be met by imports, chiefly in the form of ore from Mexico and Bolivia, as the present tariff on antimony favors the importation of ore rather than metal. Demand for antimony in the post-war period probably will exceed the pre-war level, partly because of the large requirements for storage batteries and other metal products and also because of new applications developed during the war, notably the use of antimony oxide in the preparation of flame-proofing and mildew-proofing compounds for treating canvas and other textiles.

DOMESTIC MINE PRODUCTION

Only 17 antimony-producing mines operated in 1943 compared with 31 in 1942, but a record output of 5,637 tons of antimony in 16,785 tons of ore almost doubled the 1942 production of 2,944 tons. The Yellow Pine mine supplied 77 percent of the mine output and practically all of the large gain. In terms of antimony content, 4,341 tons came from tungsten-gold-antimony ore, 971 tons from silver-copper-antimony ore, 182 tons from antimony ore, and 143 tons from gold-antimony ore. Such past producing States as California, Montana, and Washington had no production of antimony ore during the year.

Alaska.—Aided by extensive exploration by the Geological Survey and the Bureau of Mines, antimony mining in Alaska showed increased activity. At least nine operators contributed 184 tons of antimony in ore during 1943. The Metals Reserve Co. purchasing depot at Fairbanks increased its holdings from 15 tons of ore (antimony content) on January 1, 1943, to 96 tons on January 1, 1944. The terms for the purchase of antimony ores in Alaska were extended to December 31, 1944. These prices were practically the same as those paid for domestic ores in the United States by Metals Reserve Co., as listed in the section of this chapter reviewing prices.

According to the Geological Survey, in 1941 the estimated reserves of proved and probable antimony ore in the Stampede Creek area, 120 miles southwest of Fairbanks, were 70 tons of 50-percent or better ore, 6,000 tons of 10- to 15-percent ore, 1,000 tons of 20-percent ore as loose material below the surface ore body, and 5,000 tons of mill tailings carrying about 6 percent antimony. The ore consists of lenses and veins of stibnite disseminated in quartz veins as veinlets in schist.

In the summer of 1942 the Bureau of Mines completed a successful exploration of the Mooney ore shoot of Earl Pilgrim's Stampede mine in the Kantishna district. As a result of mining this antimony ore and reprocessing some accumulated tailings, Stampede continued to be the largest producer in Alaska.

The Slate Creek mine, also in the Kantishna district, owned by Ernest Maurer, was the only other large operation and produced 90 tons of ore averaging 47 percent antimony.

Several promising areas were investigated by the Geological Survey. These included a stibnite deposit at Caamano Point, Cleveland Peninsula, and the quicksilver-antimony deposits in the Sleitmut area of the Georgetown district. Signs of mining activity were apparent in the Wood River area and the Tok River area. Several individuals collected small quantities of antimony ore stored at the gold-antimony mines in the Fairbanks district and shipped the material to the Fairbanks purchase depot.

Idaho.—Practically all of the domestic antimony ore is mined in Idaho, and in 1943 past production records were topped with a State total of 5,231 tons of antimony contained in concentrates produced.

The Yellow Pine mine at Stibnite, owned and operated by the Bradley Mining Co., has become one of the largest antimony mines in the world, with a 1943 output of 9,930 tons of antimony concentrates containing 4,341 tons of metal. The stibnite containing the antimony is intimately associated with scheelite, pyrite, arsenopyrite, gold, and silver. An urgent war need for tungsten effected a very large increase in activity at the Yellow Pine mine, and because of the nature of the deposit a considerable quantity of antimony was removed along with the tungsten. The ore was mined from an open pit and treated by flotation which yielded a scheelite concentrate, a gold concentrate, and an antimony concentrate averaging 50 percent antimony and 4.5 ounces of silver and 0.057 ounce of gold per ton. About one-third of the antimony mined remained unrecovered in the flotation tailings. As a result of the completion of a 106-mile power line carrying 66,000 volts of electricity into Stibnite the company plans to increase the 700-ton daily milling capacity to 1,000 tons.

In the Coeur d'Alene district antimony is recovered from complex "dry belt" ores such as tetrahedrite valued principally for its silver. The largest producers in this area were the Sunshine Mining Co. in Kellogg and the Coeur d'Alene Mines Corporation in Wallace. Sunshine operated a 1,200-ton concentrator, and Coeur d'Alene had a 600-ton mill. Most of this concentrate was directed to the new electrolytic plant of the Sunshine Mining Co. and refined into cathode metal.

The Polaris Mining Co. in Wallace produced silver-copper and silver-iron concentrates containing 53 tons of antimony.

Nevada.—Antimony-mining activity in Nevada showed a marked decrease during 1943. B. E. Gallagher operated the Antimony King mine, Sam Watkins the W. P. mine, Tony Romano and Robert Roecker the Bray mine, Anna Rechel the Happy Returns property, Lillie Pesi the Apex mine, and William Choate a mine in Washoe county. These six operators produced 84 tons of ore containing 32 tons of antimony, a sharp drop from the 1942 output of 305 tons containing 96 tons of metal.

Oregon.—This State made an excellent showing with 107 tons of antimony in 632 tons of ore mined. About 89 tons of this antimony was in gold-antimony ore from the Gray Eagle mine in the Virtue district, Baker County. This mine was owned by Pat O'Brien but operated in turn by Smith, Hubbard, Larson, and Estes until the middle of the year, when it was bought by Anthony Brandenthaler.

Emerson Merrick operated the Blue Jay mine on the Applegate River near Medford and produced 34 tons of stibnite concentrates averaging 51 percent antimony.

Utah.—With the aid of a Reconstruction Finance Corporation mine loan the Dry Lake Mining Co. was able to produce 6 tons of ore averaging 50 percent antimony. This mine, in Hunsaker Canyon, Brigham City, was the only active one in the State.

CONSUMPTION AND PRODUCTION BY SMELTERS AND MANUFACTURERS

Primary antimony raw materials were consumed by smelters that produce antimony metal, oxide, and sulfide and by manufacturers that make finished metal and nonmetal products. Together the smelters and manufacturers used 23,505 tons (antimony content) of antimony ore in 1943—7 percent higher than 1942. More than 56 percent (13,224 tons) of the antimony ore consumed in 1943 was mixed or oxide ore, virtually all of which originated in Mexico.

Antimony ore and concentrates at smelters and manufacturers in 1943

[Short tons of contained antimony]

Raw materials	Stocks on Dec. 31, 1942	Net receipts	Consumption	Stocks on Dec. 31, 1943
Chemical-grade sulfide ore	860	4,193	4,716	337
Metallurgical-grade sulfide ore	763	1,857	2,220	400
Mixed or oxide ore	1,139	12,988	13,224	903
Sulfide concentrates	1,078	2,965	2,482	1,561
Tetrahedrite concentrates	50	813	863	-----------
Total ore	3,890	22,816	23,505	3,201

Smelter production.—Eleven plants consumed approximately 22,400 tons of primary antimony materials, including 18,457 tons of antimony in ore, and produced 20,624 tons of antimony metal, oxide, and sulfide. The Bureau of Mines is not at liberty to publish separate figures for production of these three products. Antimony metal was produced in the United States at four plants, oxide was manufactured at seven plants, and sulfide at five plants. Capacity operations were prevented at several plants by labor shortages, but output exceeded that of 1942 by 20 percent.

Texas Mining & Smelting Co., Laredo, Tex., the largest antimony smelter in the country, continued to use almost entirely the oxidized antimony ores from Mexico in the production of metal, oxide, and sulfide. Granulated cathode metal averaging 96 or 97 percent antimony was the end product of the electrolytic refinery of the Sunshine Mining Co., Big Creek, Idaho. This refinery is the newest in the country (having started operations in September 1942) and treats tetrahedrite ores obtained from its own mines and from the Coeur d'Alene Mines Corporation. At the beginning of 1943 Bunker Hill & Sullivan Mining & Concentrating Co., Kellogg, Idaho, produced antimony metal at its electrolytic refinery from complex tetrahedrite ores but later in the year changed over to Yellow Pine stibnite concentrates. The El Segundo (Calif.) plant of the Harshaw Chemical Co. smelted stibnite concentrates from the Yellow Pine mine and produced both metal and oxide. The Elyria (Ohio) plant of Harshaw Chemical Co. manufactured antimony oxide and sulfide from metal and chemical grade sulfide ore. At Perth Amboy, N. J., the American Smelting & Refining Co. has a relatively new and unique plant which made antimony oxide from antimonial lead and produced impure antimony metal by reduction of flash-roasted sulfide concentrates. Other plants producing antimony oxide and sulfide were American Smelting & Refining Co., Omaha, Nebr.; McGean Chemical Co., Cleveland, Ohio; Metal & Thermit Corporation, Carteret, N. J.; Rare Metal Products Co., Belleville, N. J.; and Ceramic Color & Chemical Manufacturing Co., New Brighton, Pa.

Production by manufacturers.—In 1943 over 300 plants consumed 19,691 tons of primary antimony raw materials, including 5,048 tons of antimony in ore, and produced 19,508 tons of finished products which are listed in the following table. Slightly more primary antimony was recovered in nonmetal than in metal products. Flameproofing of canvas for such military uses as tents, tarpaulins, camouflage netting, and life preservers proved to be the largest end use for primary antimony. The consumption of antimony in frits and ceramic enamels was sharply curtailed by the exigencies of war.

Production of finished products containing antimony in 1943

[1] Partly estimated.

The primary lead smelters produced 63,515 tons of antimonial lead containing 3,371 tons of antimony. The antimony content dropped to 5.3 percent, largely because of the increased quantity of antimonial lead low in contained antimony produced for bullet-core rod. The distribution of the antimony according to source showed some interesting changes. In 1943, 55 percent of the antimony in antimonial lead produced at primary lead smelters was derived from domestic ore, 32 percent from scrap, and 13 percent from foreign ore compared with 68 percent from domestic ore, 7 percent from scrap, and 25 percent from foreign ore in 1942. The total primary antimony recovered in antimonial lead at lead smelters and all other plants amounted to 4,664 tons in 1943.

Antimonial lead produced at primary lead refineries, 1939–43, in short tons

Year	Production	Antimony content				
		From domestic ores [1]	From foreign ores [2]	From scrap	Total	
					Quantity	Percent
1939	21, 995	929	179	923	2, 031	9. 2

[1] Includes primary residues and small quantity of antimony ore.
[2] Includes foreign base bullion and small quantity of foreign antimony ore.

STOCKS

Combined producer and consumer inventories of antimony ore, concentrates, metal, oxide, and sulfide decreased 14 percent from 9,440 tons on December 31, 1942, to 8,089 tons on December 31, 1943. Augmenting the total industry-owned stocks of 8,089 tons of primary materials on hand December 31, 1943, were mine stocks of 3,826 tons and Metals Reserve stocks of 10,511 tons of foreign ore, 159 tons of domestic ore, and 12,848 tons of antimony metal. Thus the supply of raw materials available for the manufacture of finished products totaled 35,433 tons (antimony content) at the end of 1943 compared with 24,425 tons at the end of 1942.

SECONDARY PRODUCTION

A detailed review of the secondary antimony industry is presented in the Minerals Yearbook chapter on Secondary Metals—Nonferrous. The recovery of secondary and primary antimony in finished products during the year totaled 15,483 tons from scrap and 19,508 tons from primary materials. Almost two-thirds of the antimony in metal products was derived from scrap. Old battery lead plates continued to supply the bulk of this secondary antimony.

PRICES

The price of domestic brands of antimony metal was quoted at 16.049 cents a pound for less than carlots in New York from January 1 through June 2. As a result of permission to ship antimony from Laredo, Tex., to Jersey City, N. J., at transcontinental freight rates a reduction of $3.74 per ton in freight charges was passed on to the buyers. Thus the New York price has been quoted at 15.839 cents a pound since June 3 and continued throughout the remainder of 1943. Carlot prices opened the year at 15.509 cents a pound and dropped to 15.452 cents on May 15 and again to 15.265 cents on June 3. Virtually no Chinese metal was available in 1943, and the purely nominal price of 16.50 cents in effect since November 1939 remained unchanged in 1943.

A base ceiling price of 14.50 cents a pound for 99- to 99.8-percent antimony metal was established by the Office of Price Administration under the new Price Regulation MPR-497, effective December 9, 1943. Imported antimony metal and domestic metal have the same maximum price, and 15 other compounds (including the oxide and sulfide) were put under this new regulation. Previously the antimony price

Average monthly quoted prices of antimony, prompt delivery at New York, 1939-43, in cents per pound, for less than carlots

[1] From daily issues of American Metal Market, except 1939, which was taken from Metal Statistics, 1940, p. 529.

[2] Metal Statistics, 1944, p. 559.

[3] Nominal.

was governed by the General Maximum Price Regulation based upon the highest prices charged during March 1942.

Prices for English regulus (minimum 99-percent antimony) and foreign regulus (spot deliveries from warehouse) remained unchanged throughout 1943 at £120.

Quotations for antimony ore and concentrates on January 1, 1943, according to E. & M. J. Metal and Mineral Markets, were as follows: "Per (short-ton) unit of contained antimony, at New York, 50 to 55 percent, $2.10 @ $2.20; 58 to 60 percent, $2.15 @ $2.20; 60 to 65 percent, $2.20 @ $2.30. London, 60 to 65 percent, 12s. 6d. per long-ton unit, nominal." These prices remained unchanged throughout 1943.

The following rates per short-ton unit of contained antimony were paid by the Metals Reserve Co. for domestic antimony ores delivered at a purchase depot: 20-percent ore, $1.15; 25-percent, $1.40; 30-percent, $1.65; 40-percent, $1.75; 50-percent, $1.85; 55-percent, $1.925; 60-percent, $2.00; 70-percent, $2.15.

WAR AGENCY REGULATIONS

The War Production Board continued to coordinate antimony supply and demand in 1943 by means of General Preference Order M-112. An amended version of this order, issued March 8, relaxed restrictions on the use of antimony in automotive battery plates and other approved alloys. Privilege was also granted to use antimony in any form for manufacture of white pigments, opacifiers, and frits for non-acid-resisting ceramic enamels. No change was made in the 50-ton limit on the permissible antimony content of unallocated ores and concentrates, but the maximum size of unallocated deliveries of antimony metal and alloys was raised from 25 pounds to 2,240 pounds a month.

Effective February 1, 1943, antimony was reclassified from group II to group III of the Material Substitutions and Supply List of strategic minerals. Group II is composed of essential war materials, supplies of which are in balance with immediate demand, and group III includes materials available in significant quantities, which are particularly recommended as substitutes for critical materials.

The improved position of antimony became apparent when it was removed from allocation control of the War Production Board by amendment to General Preference Order M-112 on December 4, effective January 1, 1944. Consumers were still required to file reports of their activities with the War Production Board upon a quarterly instead of monthly basis.

TECHNOLOGIC DEVELOPMENTS

As a result of the war there has been an unprecedented demand for canvas that is flameproof, waterproof, and mildew-resistant. Canvas is endowed with these characteristics by dipping it into a compound containing antimony oxide, chlorinated paraffin, paint pigments, and several other constituents. The treated canvas will burn if heat is supplied from an external source, but it will not support combustion after the source of heat is removed. A fireproof adhesive cement of similar composition has been developed to hold fiber-glass insulating walls to the steel partitions and sides of Navy ships.

Because infrared photography revealed most camouflage painting it has been necessary to develop paints with the same infrared reflectance characteristics as the surrounding green foliage. Chromium oxide and antimony sulfide are the two most important dark pigments with these characteristics, which make them essential for use in camouflage paints.

Before the war antimony in solder was usually considered an impurity rather than an alloying agent. However, the present shortage of tin has led to the substitution of antimony for tin in some solders. A general rule defining this practice is that the tin content can be reduced 2 percent for each percent of antimony added until the antimony reaches 6 percent of the tin content. One of the most popular "war" solders analyzes 2 percent antimony, 30 to 40 percent tin, and the remainder lead.

In 1942 the Metalurgica de Mexico, S. A., completed a unique smelter at Tlalnepantla, Mexico. This smelter was designed to recover antimony, mercury, and tin from complex Mexican ores, such as livingstonite ($HgS.2\ Sb_2S_3$). A concentrate of this ore is burned in a special sintering machine. The vaporized mercury is collected in a condenser, and the antimony sinter is treated in a blast furnace equipped with two crucibles interchangeable for antimony and tin.

Briefly, the new Sunshine Mining Co. electrolytic refinery produces antimony cathode metal in the following manner. The antimony contained in the tetrahedrite ore is put into solution by leaching 8 to 10 hours at 100° C. in a solution of Na_2S. After filtering, the pregnant solution is electrolyzed in diaphragm-type cells containing mild-steel anodes and cathodes. The resultant cathode metal contains about 96 or 97 percent antimony and is sold as such without further refining.

Several interesting patents concerning antimony were issued during the year. One involved partial removal of antimony from antimonial lead containing no tin by stirring litharge into the molten alloy. The antimony is oxidized and enters into a slag that can be easily withdrawn from the metal. Another patent removes antimony from lead-tin alloys by adding aluminum, magnesium, sodium, potassium, or calcium to the molten alloy. The antimony combines with the added metal to form an intermetallic compound of relatively high melting point, which rises to the surface and is skimmed off as a mushy dross. The antimony may be reclaimed by grinding the dross, heating it in a kiln through which a current of steam passes, and collecting the resulting antimony oxide in a bag house. A patent was issued for reduction of impure antimony trioxide to the metallic form. The oxide is mixed with about 12 percent carbon, put in a crucible made of a slag composed of approximately equal parts of sodium sulfate and common salt, sealed with hot slag, and heated to 1,300° C. in a reverbatory furnace to produce antimony metal with practically no volatilization loss. A new method for producing tartar emetic was accomplished by mixing finely divided antimony metal with nitric acid and potassium bitartrate. Boiling and refluxing this mixture, followed by evaporation and cooling, yield tartar emetic.

FOREIGN TRADE [1]

The following tables show imports and exports of antimony materials.

Antimony imported for consumption in the United States, 1939–43

Year	Antimony ore			Needle or liquated antimony		Antimony metal		Antimony oxides and other compounds	
	Short tons	Antimony content		Short tons	Value	Short tons	Value	Short tons	Value
		Short tons	Value						
1939	21,000	9,448	$1,132,359	228	$30,102	1,045	$196,812	173	$29,786
1940	37,966	15,733	2,027,612	113	19,464	209	50,048	5	1,851

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Foreign antimony (regulus or metal) exported from the United States, 1939–43

Year	Short tons	Value	Year	Short tons	Value
1939	58	$16,736	1942	(1)	$181
1940	276	75,440	1943	(1)	200
1941	70	19,690			

[1] Less than 1 ton.

The United States continued to depend on foreign sources for its supply of antimony ore.

Bolivia provided the United States with 13,833 short tons (antimony content) of chemical-grade and metallurgical-grade sulfide ores in 1943, an 88-percent increase over 1942. The chemical-grade sulfide ore serves as an excellent raw material for the production of antimony oxide, but the metallurgical-grade ore is better-suited for use in making antimonial lead alloys. Since most of this high-grade ore has been placed in the Government stock pile, Metals Reserve Co. (the Federal purchasing agent) has curtailed to a minimum the 1944 purchases from Bolivia.

From Mexico came 12,673 tons of antimony in ore and 643 tons of metal. Virtually all the ore from Mexico was in the oxidized form.

As a result of the treatment of a large accumulation of lead-smelter flue-dust residues, Peru was able to ship 289 tons of metal as well as 2,131 tons in ore in 1943.

In addition to the actual receipts from Bolivia and Peru, a stock pile of 11,498 tons of antimony in concentrates purchased from these countries by the Metals Reserve Co. and awaiting shipment to this country was stored in Chile.

Total exports in 1943 included 291 tons of antimony metal, 95 tons in oxide, and 17 tons in sulfide.

WORLD PRODUCTION

Despite war censorship, a few more production figures were made available by foreign countries for past years, as well as for 1943. Information from Europe and Asia continued to be very meager. Several interesting figures on past production were obtained for Spain, Spanish Morocco, Czechoslovakia, Union of South Africa, and Southern Rhodesia. Data for North and South American output were practically complete. The Allies controlled about 80 percent of the world ouput, Yugoslavia, Czechoslovakia, and parts of China being the only large producers under Axis domination.

REVIEW BY COUNTRIES

Argentina.—The small requirements for antimony were met here by approximately 200 to 300 metric tons of domestically mined stibnite, supplemented by imports from Bolivia. Most of the ore came from the Pabellon mine at 14,500 feet altitude in the Cerro Granadas, Department of Rinconada, Province of Jujuy.

Australia.—The principal ore of antimony in Australia is stibnite, but cervantite, tetrahedrite, jamesonite, and bournonite also occur in appreciable quantities. Antimony sulfide was prepared by liquation from high-grade handpicked stibnite at the plant of O. T. Lempriere & Co., Ltd., Alexandria, Sydney, New South Wales. The

World production of antimony, 1937–43, by countries, in metric tons [1]

stibnite concentrates, which contain little or no gold, were treated at the same plant for production of metallic antimony, antimony oxide, and sodium antimonate.

Refined antimonial lead was made by the Electrolytic Refining & Smelting Co., Port Kembla, New South Wales, from antimonial slag resulting from smelting lead ores and refining bullion.

Most of the antimony formerly came from the Wiluna mines in Western Australia, but recent exhaustion precludes any production in 1943. Small, high-grade parcels of sulfide ore were obtained by selective mining from the Blue Spec mine in this vicinity. Antimony occurs as complex sulfides in lead ores at Broken Hill, from which source antimonial slag containing about 490 tons of antimony was produced for subsequent smelting.

Australian consumption averages about 1,000 tons of primary antimony as metal, in oxide, sulfide, sodium antimonate, and antimonial lead.

Bolivia.—More antimony ore was mined in Bolivia than in any other country in the world during 1943. The large number of small mines are located in the district of Tupiza, Department of Potosí, and Challapata, Department of Oruro. The stibnite ore occurs in quartz veins traversing narrow belts of fractured black slate. Much of the ore is wasted by primitive mining methods and by hand sorting to produce high-quality chemical-grade and metallurgical-grade concentrates. The ore is sold to the Banco Minero de Bolivia, which exports it to the foreign market.

In February 1943 the Metals Reserve Co., acting for the United States Government, signed a contract for the purchase of 9,000 tons of antimony in chemical-grade concentrates and 5,000 tons in metallurgical-grade concentrates. The 1944 Metals Reserve Co. contract calls for 5,000 tons of antimony in chemical-grade concentrates and no metallurgical-grade. As a result of this decrease in demand, many of the mines that could produce only metallurgical-grade concentrates were forced to close. As an emergency measure the Banco Minero has agreed to continue purchasing chemical-grade and also metallurgical-grade containing a minimum of 60 percent antimony and maximum of 1 percent lead and arsenic until March 31, 1944.

Near the end of April 1943 the Bolivian Government reduced the export tax on all mineral shipments except antimony, perhaps directing its tax policy toward discouragement of high antimony production.

Canada.—Canadian output was limited to a small quantity of electrolytic antimony made by the Consolidated Mining & Smelting Co. at Trail, British Columbia.

China.—Antimony production is reported to have ceased in Kwangsi during 1943. Mining villages were deserted, and mine owners were liquidating assets and selling machinery as scrap. A stock pile estimated to contain 31,000 metric tons of antimony had been accumulated between Kweilin and Kunming.

Between 70 and 80 percent of the Chinese antimony reserves are in Hsikuangshan, Singhua district, Hunan Province. Known reserves of China total 2,446,000 to 3,677,000 tons of contained antimony.

Czechoslovakia.—Czechoslovak refined-metal production in 1941 was estimated at 1,645 tons. A rapidly increasing supply of ore is coming from the mines near Bosing and Mezibroddon Allehota.

Honduras.—The largest active mine in Honduras is the El Quetzal, near San Augustin de Copan, owned by Manuel Bueso and Rodolfo Nater. The ore body is stibnite (partly oxidized near the surface), pyrite, and quartz and is mined from open-cuts. Production of the mine in 1941–43 was 450 tons of concentrate, averaging 58 to 62 percent antimony. The concentrate is transported with difficulty to the port of San José, Guatemala, where it is exported by Casa Bueso. La Union mine in the Department of Olancho has been active, as well as one near the town of Yoro and two others in the Department of Copan.

Italy.—The principal antimony property in Italy is the Su Suergiu mine in southeastern Sardinia. Other deposits are the Corti Rosas mine near Ballao and several in Sicily and northern Italy. A smelter operated at Villacidio in Sardinia produced antimony oxide and metal. Another smelter was built in 1940 at Rosia near Siena.

Japan.—Large deposits of antimony ore are reported to have been located at copper mines in the neighborhood of the town of Sapporo on Hokkaido Island.

Mexico.—Conversion of the mine of Compañía Minera de Oaxaca, near St. Juan Mixtepec, from underground to open-pit operations was completed early in 1943, but after a few months it was found advisable to return to underground methods because of the increased proportion of waste to be handled.

The new Tlalnepantla smelter of the Metalurgica de Mexico, S. A., commenced to produce metallic antimony, and Metals Reserve Co. agreed to buy the output.

Depletion of reserves and the lower price of mercury closed the Huitzuco livingstonite mine in Guerrero early in 1944.

Nova Scotia.—Antimony Mines, Ltd., has acquired the rights to work antimony mines near Rawdon from the St. Helena Mining Co. The seam is 7 inches wide, and recent samples assayed 40 to 55 percent antimony and 3.48 to 3.83 ounces of gold per ton.

Peru.—The Cerro de Pasco Copper Corporation had a large stock pile of flue dust containing bismuth and antimony at its Oroya lead smelter. A special plant for recovering these metals was completed in August 1942 and produced an impure metal containing 95 to 96 percent antimony. About 289 tons of this metal were shipped to the United States in 1943.

About half of the Peruvian antimony is mined in the Department of Puno, where the deposits are stibnite ore shoots in quartz veins traversing slate belts.

The Over-all Metals and Minerals Agreement between the Peruvian Government and the Metals Reserve Co. was signed in Lima on July 20, 1943, effective until June 30, 1944. The maximum quantity of antimony that Metals Reserve Co. agreed to purchase was not to exceed 100 percent of the 1942 exports produced in Peru, and the price was to be $2.10 per short-ton unit of antimony content, f. o. b. steamer, for chemical-grade ore.

Russia.—The antimony industry seems to have been untouched by the war. Antimony was mined and processed at Kadamdzhai in Osh oblast of Kirgizia and in Kazakhstan. The concentrates were smelted at the antimony-mercury combine at Frunze in Kirgizia and in a plant at Uzbekistan.

Union of South Africa.—The Consolidated Murchison mine in the Murchison Range, Transvaal, shipped 2,053 tons of antimony concentrates averaging 54 percent antimony in 1942 and operated at a rate close to 300 tons of concentrates per month in 1943. The deposits are argentiferous and auriferous and are mined principally for the gold. The concentrates assayed about 52 percent antimony, 0.59 percent arsenic, 0.09 percent nickel, 0.1 percent copper, a trace of lead, and 5 ounces of gold per ton.

Yugoslavia.—According to the December (1943) issue of Mineral Trade Notes, Podrinski Udruzani Rudnice was producing 100 to 120 metric tons of pure antimony monthly under German control. The Loznica mine was also controlled by Germany.

CADMIUM

By Allan F. Matthews

SUMMARY OUTLINE

	Page		Page
General statement	791	Stocks	794
Domestic production	791	Prices	795
Foreign trade	793	World aspects	795
Consumption and uses	793		

GENERAL STATEMENT

Cadmium was one of the few nonferrous metals to retain its critical position in 1943. In the latter half of 1943 there was a significant increase in the consumption of cadmium for bearings and chemicals and a decided decrease in cadmium consumption for electroplating, solders, and alloys. On July 26, 1943, the War Production Board issued Conservation Order M–65–a, as amended, to prohibit the use of cadmium in pigments, except for specific purposes, most of which are military. The Office of Price Administration ceiling price of 90 to 95 cents a pound remained in effect during 1943 (Schedule 71).

Salient statistics of the cadmium industry in the United States, 1939–43, in pounds

	1939	1940	1941	1942	1943
Production (primary)	4,790,500	6,363,600	7,233,500	7,370,969	8,466,963

[1] Data not available.

[2] Apparent consumption.

DOMESTIC PRODUCTION

The production of primary cadmium surpassed the record output of 1942 by more than a million pounds, and shipments by producers advanced 16 percent. Geographic distribution of the primary cadmium production, based upon the location of plants that produced metal or compounds, was as follows in 1943: 69 percent from 4 plants in four Western States, 22 percent from 11 plants in six Central States, and 9 percent from 6 plants in four Eastern States. Domestic production is about half from domestic zinc and lead ores and about half from imported concentrates and flue dust. A decrease in production during 1944 is predicted, because a decline of smelter operations probably will follow the anticipated induction of men into the armed forces. The Corpus Christi plant of the American Smelting & Refining Co. began to produce cadmium in February 1943.

Cadmium produced and shipped in the United States, 1939–43, in pounds

	1939	1940	1941	1942	1943
Production:					
Primary: [1]					
Metallic cadmium	4,411,530	6,154,200	6,937,931	7,323,346	8,396,292

Total value	2,988,860	4,671,212	5,705,650	5,802,030	6,679,390

[1] Figures showing primary cadmium production for 1940–43 are strictly comparable. The data for 1939 are exactly comparable with 1940–43 as to totals, but in the former period the cadmium content of some compounds made from metal is included with the compounds and excluded from the metal.

[2] Excludes compounds made from metal.

[3] Some secondary compounds included with primary compounds; Bureau of Mines not at liberty to publish figures separately for primary cadmium compounds.

[4] Bureau of Mines not at liberty to publish figures separately for secondary cadmium compounds.

[5] Data not available.

[6] Figures for 1939 represent sales.

A large quantity of the cadmium-compound output is from metal, although some is produced directly from primary residues and secondary metal. Owing to conservation measures, the total production of cadmium compounds (in terms of Cd content) decreased 19 percent from 1942.

Cadmium compounds produced in the United States, 1941–43, in pounds

Compound	1941		1942		1943	
	Gross weight	Cd content	Gross weight	Cd content	Gross weight	Cd content
Sulfide [1]	3,304,478	1,141,500	1,001,124	300,414	671,831	227,045
Oxide [2]	410,748	361,300	594,018	519,586	511,382	447,143

Total production	4,020,965	1,651,400	1,665,887	859,726	1,219,090	693,648

[1] Includes cadmium lithopone and cadmium sulfoselenide.

[2] In addition to quantities shown, cadmium oxide consumed in making other compounds shown was produced as follows: 1941, 36,649 pounds (Cd content, 27,500 pounds); 1942, 38,721 pounds (Cd content 33,881 pounds); 1943, 25,975 pounds (Cd content, 22,833 pounds).

[3] Bromide included with hydrate to avoid disclosure of confidential figures.

[4] Iodide included with hydrate to avoid disclosure of confidential figures.

FOREIGN TRADE [1]

Imports.—Cadmium-metal imports from the Belgian Congo declined in 1943 compared with 1942, partly because of reduced production and also because 6,000 pounds were lost in January by enemy submarine attack. The beginning of imports from Peru was somewhat compensatory. Domestic cadmium production is partly from imported Mexican flue dust, which contained 1,643,404 pounds in 1943 compared with 1,723,728 pounds in 1942.

Exports.—Cadmium exports totaled 169,265 (153,637 of metal and 15,628 in compounds) in 1943 compared with 283,630 pounds (251,059 of metal and 32,571 in compounds) in 1942 and 171,858 pounds (65,851 of metal and 106,007 in compounds) in 1941 and 387,118 pounds (286,529 of metal and 100,589 in compounds) in 1940. The Bureau of Mines compiled these figures from exporters (except that the figures for compounds in 1943 and 1942 were estimated from data for gross weight obtained from the United States Department of Commerce); corresponding data for previous years are not available. Through Lend-Lease agreement Russia received all but an insignificant quantity of the cadmium metal exported in 1943 and 1942.

Metallic cadmium imported for consumption in the United States, 1939–43

CONSUMPTION AND USES

Consumption of cadmium in the United States decreased 4 percent in 1943 compared with 1942 as a result of Government conservation and stock-piling measures.

Consumption of cadmium in the United States, 1940–43, by uses

Use	1940		1941		1942		1943	
	Pounds	Percent of total	Pounds	Percent of total	Pounds	Percent of total	Pounds	Percent of total
Electroplating	3,692,000	60	4,586,000	59	6,661,000	87	6,481,000	88
Bearings	1,300,000	21	1,504,000	19	282,000	4	249,000	3

---

[1] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Electroplating.—Nine-tenths of the United States cadmium consumption is used to electroplate protective coatings on steel articles and parts. Of the cadmium required for this purpose in July through November 1943, according to the War Production Board, 39 percent was for aircraft frames, 17 percent for aircraft engines, 14 percent for ammunition, 6 percent for other ordnance, 10 percent for communications, 5 percent for ships, 6 percent for other military equipment, and 3 percent for civilian use. Strenuous efforts were made throughout the year to substitute coatings of zinc, lead, and other materials for cadmium plating.[2]

Alloys.—Certain bearings containing over 95 percent cadmium and small quantities of nickel, silver, and copper are made for heavy-duty applications. Of the cadmium allotted for bearings in July through November 1943, according to the War Production Board, 53 percent was for civilian use, 21 percent for ships, 8 percent for aircraft, 7 percent for ordnance, 8 percent for other military purposes, and 3 percent for export. Cadmium additions lower the melting point of solders and of fuse metal. Copper alloyed with small quantities of cadmium is fabricated into trolley wire and welding rods.

Compounds.—Cadmium sulfide and cadmium sulfoselenide are standard agents for imparting bright, resistant yellow and red, respectively, to paints, ceramics, inks, rubber, leather, and other products. Cadmium-zinc sulfide is an important phosphor for luminizing maps and aircraft dials.[3] Cadmium oxide, hydrate, and chloride are used in electroplating solutions; the fluoborate is a newcomer in this field. Cadmium carbonate is used in ceramics, and the halides in photography.

STOCKS

Total stocks of cadmium in the United States increased 48 percent over 1943 because of the advance in the Government stock pile. Stocks of metallic cadmium held by producers, compound manufacturers, and consumers declined 5, 11, and 28 percent, respectively. Distributors more than doubled their stocks, and the Government stock pile increased sevenfold over 1942.

Cadmium stocks at end of year, 1942–43, in pounds

	1942 [1]			1943		
	Metallic cadmium	Cadmium compounds (Cd content)	Total cadmium	Metallic cadmium	Cadmium compounds (Cd content)	Total cadmium
Producers	387,573	88,994	476,567	431,608	22,573	454,181
Compound manufacturers	11,595	123,777	135,372	31,059	89,913	120,972
Distributors [2]	131,443	28,310	159,753	445,328	36,529	481,857
Consumers [3]	1,283,000	83,000	1,366,000	911,000	69,000	980,000
Government	200,946		200,946	1,429,625		1,429,625
Total stocks	2,014,557	324,081	2,338,638	3,248,620	218,015	3,466,635

PRICES

The Office of Price Administration ceiling price of 90 cents a pound for metallic cadmium sticks and 95 cents a pound for anode shapes prevailed throughout 1943. Shipments of metallic cadmium, as reported to the Bureau of Mines by primary producers, retained the 1942 value of 79 cents a pound in 1943 compared with 78 cents in 1941. Producers' quotations, according to E&MJ Metal and Mineral Markets, averaged 90 cents in 1943 compared with 90 cents in 1942 and 88 cents in 1941.

Prices for compounds as quoted by Oil, Paint and Drug Reporter were $1.65 to $1.91 a pound for cadmium bromide, $0.85 to $1.00 for cadmium lithopone red, 55 to 65 cents a pound for cadmium lithopone yellow, and $1.10 for cadmium sulfide.

WORLD ASPECTS

World production of cadmium in recent years, insofar as data are available, is shown in the following table.

World production of cadmium, 1938–43, by countries, in kilograms

[Compiled by B. B. Waldbauer]

[1] Data not available; in 1939 and 1940, estimate included in total. [2] Estimate. [3] Exports.

[4] Cadmium content of flue dust exported for treatment elsewhere; represents in part shipments from stocks on hand. To avoid duplication of figures, the data are not included in the total.

[5] Figures cover January to June, inclusive.

Australia.—The United States Board of Economic Warfare in May 1943 estimated that during the year 280 metric tons of metallic cadmium would be produced by the Electrolytic Zinc Co., Risdon, Tasmania, from Broken Hill zinc concentrates (265 tons) and Port Pirie (South Australia) lead furnace baghouse fume. An additional 200 tons in Mount Isa (Queensland) fume was available for refining in Australia or the United States.

Belgian Congo.—Zinc sulfide concentrates from the Prince Leopold mine at Kipushi, southwest of Elizabethville, are roasted in Dwight-Lloyd sintering machines by Union Minière du Haut Katanga to yield sulfuric acid for the Jadotville electrolytic copper refinery. The roasting liberates part of the cadmium, which is recovered as flue dust and then refined at Jadotville by Sóciéte Générale Industrielle et Chimique du Katanga ("Sogechim"), a subsidiary. The cadmium output—at a comparatively high level in 1942–43 because of using up an accumulation of zinc dust and because of the strong demand for acid—is expected to decline to a normal level of 13 metric tons in 1944.

Belgium.—Produits Chimiques de Tessenderloo, S. A., whose plant was seriously damaged by an explosion April 29, 1942, had reestablished its electrolytic department by early 1943.[4]

Canada.—Exports of cadmium were 259,551 kilograms (572,215 pounds) in 1943 compared with 363,194 kilograms (800,710 pounds) in 1942. The output is by Consolidated Mining & Smelting Co. of Canada, Ltd., Trail, British Columbia, and Hudson Bay Mining & Smelting Co., Flin Flon, Manitoba. Canadian metallic cadmium, ton lots, was quoted at $1.30 a pound throughout 1943, according to Canadian Metals and Metallurgical Industries.

Mexico.—Cadmium flue dust is produced at the Rosita, San Luis, and Chihuahua smelters of the American Smelting & Refining Co. and is exported for refining at the Globe plant (Denver, Colo.) of the same company. Flue dust is also recovered at the Monterrey and Torreón smelters of the American Metal Co., Ltd.

Peru.—Cadmium production was begun early in 1942 by the Cerro de Pasco Copper Corporation at Oroya.

Spain.—Production of about 500 kilograms of cadmium annually is planned by the Real Compañía Asturiana de Minas—the principal zinc producer—whose ores in the Santander region contain 0.15 percent Cd.

United Kingdom.—Cadmium requirements of the war industries are met by imports from the Dominions—Canada and Australia. Consumption for plating has been severely restricted, and the larger part of the available supply now goes into alloys.[5] This use trend parallels that of Germany but is opposite to that of the United States. The Minister of Supply imposed license control on cadmium sales, effective January 1, 1942, and at the same time established a ceiling price for ingots, sticks, and rods at 5 s. 4 d. a pound in hundredweight lots.

SUMMARY

Despite prohibitions and limitations on the use of platinum metals for certain purposes, consumption (as measured by sales—509,232 ounces) in 1943 surpassed the record established in 1942 by 36 percent. The increase was due mainly to the larger demand for platinum for electronic tubes, contact points, and spinnerets for glass fiber, and for palladium in jewelry. Imports of platinum metals (362,251 ounces) also exceeded the high of 1942 by 15 percent. Refining of platinum metals not only did not pace consumption but dropped 8 percent below the all-time peak of 1942.

Salient statistics of platinum and allied metals in the United States, 1942–43, in troy ounces

	1942	1943
Production:

Figure 1 shows graphically the trend in world production of platinum metals from 1914 to 1942.

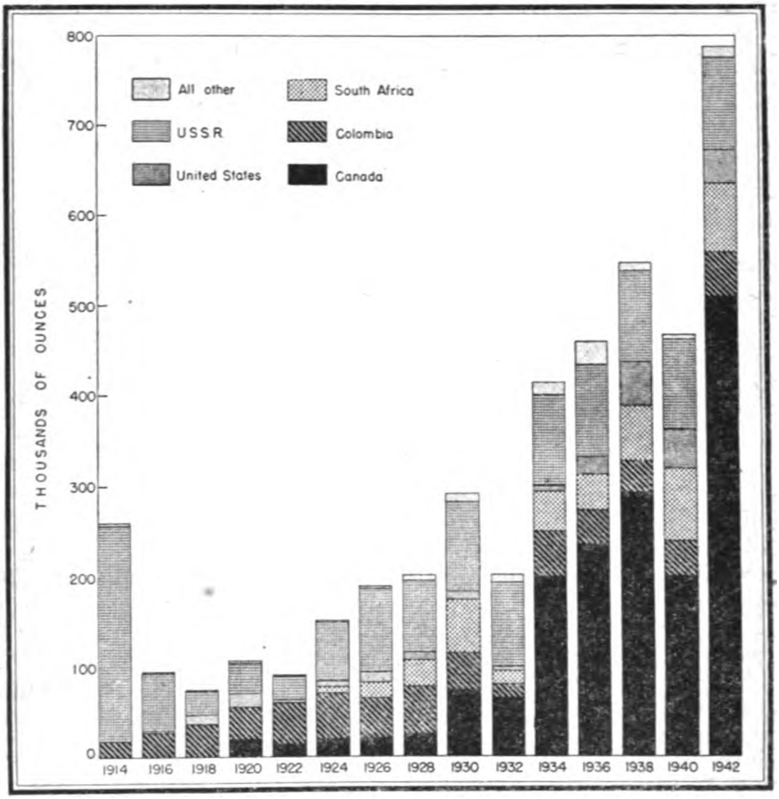

FIGURE 1.—Trend in world production of platinum metals, 1914–42.

POST-WAR OUTLOOK

The war has emphasized the importance and versatility of the platinum metals but has developed few new uses for them. Although consumption will decline substantially when the war ends, with stability in the price of the platinum metals that will permit their use for industrial purposes, coupled with developmental activities in opening up larger and more diversified markets, a post-war demand considerably greater than during the immediate pre-war years should result.

WAR REGULATIONS

The War Production Board issued a number of regulations on platinum metals in 1943. Conservation Order M–302, issued April 16, provides that osmium and osmium alloy processed after that date shall be used for implements of war only. Order M–49, as amended April 30, places iridium under complete allocation and confines its use to contact points, fuse wire for detonators, electrical primers, and laboratory ware. Order L–45, effective April 15, restricted the use of gold and palladium by large manufacturers in their production of jewelry, from April 15 through June 30, to 75 percent of their use of these metals during the same period of 1941; since July 1 the reduction has been 50 percent. Restrictions on jewelry output as provided for in Order L-45 are intended to release plant facilities and workers for war production and do not result from shortage of palladium or gold. Order M-162, as amended November 22, places restrictions on the sale and delivery of platinum scrap, prohibits delivery of platinum to processors having more than a specified amount of scrap, and limits processors' and consumers' inventories of platinum.

Maximum prices for the platinum metals were established by the Office of Price Administration in Maximum Price Regulation 309.

CRUDE PLATINUM

Production.—Mine returns for 1943 indicate a production of 27,100 ounces of crude platinum (containing 23,900 ounces of platinum-group metals) in Alaska[1] and 62 ounces in California—a total of 27,162 ounces; comparable figures for 1942 are 22,000 ounces of crude platinum (containing 19,360 ounces of platinum-group metals) in Alaska, 1,200 ounces in California, and 13 ounces in Oregon—a total of 23,213 ounces. Production in Alaska came mainly from placer deposits in the Goodnews district of southwestern Alaska; most of it was mined by a large modern dredge and by well-mechanized draglines. In California the output of platinum was a byproduct of dredges working gold placers in Yuba County. There was no production in Oregon in 1943.

Many gold and copper ores in the United States contain small quantities of platinum metals. In 1943, 10,390 ounces of platinum metals were recovered as a byproduct of refining gold and copper ores compared with 9,805 ounces in 1942.

Purchases.—Buyers in the United States reported purchases of domestic crude platinum from the following sources in 1943: Alaska, 27,011 ounces; California, 1,114 ounces; and Oregon, 5 ounces—a total of 28,130 ounces (23,147 ounces in 1942). Domestic buyers also reported purchases of 39,409 ounces (53,661 ounces in 1942) of foreign crude platinum or osmiridium in 1943—15 ounces from Australia and 39,394 ounces from Colombia.

Prices.—Buyers reported purchases at $41.08 to $61.15 an ounce for domestic crude platinum and $26.69 to $90.10 an ounce for foreign crude platinum or osmiridium in 1943.

REFINED PLATINUM METALS

New metals recovered.—Reports from refiners of crude platinum, gold bullion, nickel, and copper indicate that 335,256 ounces of platinum metals were recovered in the United States from such sources in 1943, a decrease of 16 percent from the all-time record established in 1942. Of the new metals recovered in 1943, 90 percent was chiefly from concentrates from Canada and crude from Colombia, 7 percent from domestic crude (chiefly from Alaska), and 3 percent a byproduct of domestic gold and copper ores.

---

[1] Figures and other information for Alaska from Geological Survey, U. S. Department of Interior. Figures for 1943 subject to revision.

New platinum metals recovered by refiners in the United States in 1943, by sources, in troy ounces

	Platinum	Palladium	Iridium	Osmium	Rhodium	Ruthenium	Total
Domestic from—							
Crude platinum	21, 510	151	1, 932	508	265	161	24, 527
Gold and copper refining	5, 205	5, 105	47	5	20	8	10, 390
	26, 715	5, 256	1, 979	513	285	169	34, 917
Foreign from—							
Crude platinum	207, 605	77, 185	3, 307	680	6, 846	4, 716	300, 339
Nickel and copper refining							
Total recovery	234, 320	82, 441	5, 286	1, 193	7, 131	4, 885	335, 256

New platinum metals recovered by refiners in the United States, 1939–43, in troy ounces

Year	Platinum	Palladium	Iridium	Others	Total
1939	36, 033	3, 491	1, 051	866	41, 441
1940	38, 951	4, 564	1, 517	2, 307	47, 339
1941	98, 376	49, 812	1, 392	3, 043	152, 623
1942	244, 226	140, 262	5, 102	10, 737	400, 327
1943	234, 320	82, 441	5, 286	13, 209	335, 256

Secondary metals recovered.—In 1943, 101,581 ounces of secondary platinum metals were recovered from the treatment of scrap metal, sweeps, and other waste products of manufacture that contain platinum metals—a 33-percent increase over 1942.

Substantial quantities of worn-out catalysts, spinnerets, laboratory ware, and other products are returned by consumers to refiners for refining. The refined platinum metals recovered from these products (or their equivalent in refined metals) are returned to the consumers. The platinum metals so recovered are not included in the figures of secondary metals.

Secondary platinum metals recovered in the United States, 1939–43, in troy ounces

Year	Platinum	Palladium	Iridium	Others	Total
1939	45, 432	13, 039	2, 767	2, 205	63, 443
1940	47, 657	14, 773	1, 365	2, 635	66, 430
1941	37, 522	12, 630	659	758	51, 569
1942	56, 150	16, 416	1, 552	2, 493	76, 611
1943	68, 613	23, 616	2, 771	6, 581	101, 581

Prices.—Maximum prices for the six platinum metals were established by the Office of Price Administration in Maximum Price Regulation 309, effective February 1, 1943. The maximum prices per troy ounce for refined metals of a commercial purity of at least 99.5 percent were as follows: Platinum, $35; palladium, $24; iridium, $165; osmium, $50; rhodium, $125; and ruthenium, $35. Maximum prices for metals of less than 99.5 percent purity and for the platinum metals content of scrap, sweeps, and other waste products shall not exceed the highest net price the seller had in effect during the first quarter of 1942.

Properties and uses.—Much information on the platinum metals and their alloys, particularly their physical and mechanical properties and their many and diverse uses, is given in the excellent book, The Platinum Metals and Their Alloys, published in 1941 by the International Nickel Co., Inc., New York, N. Y. With slight changes and additions the following table on uses has been taken from this publication.

Uses of the platinum metals

Use	Pt	Pt Ir	Pt Rh	Pt Ru	Pd	Pd Ru	Pd Au	Pd Ag	Other platinum metals, alloys, or materials
Electrical and physical:									
Contacts for communication and other relays, magnetos, thermostats, voltage regulators, and control devices.	x	x	x	x	x			x	PtAg; WC+Pt or Os; PtAuAg; PdCu; OsIrRu; etc.
Spark-plug electrodes	x	x	x

Pivot points									RuOs with other materials.

Abbreviations: Pt, platinum; Pd, palladium; Ir, iridium; Os, osmium; Rh, rhodium; Ru, ruthenium; Au, gold; Ag, silver; WC, tungsten carbide; Cu, copper; Ni, nickel; W, tungsten; Co, cobalt.

Consumption.—As pure metals, combined, clad, or alloyed with other metals, the platinum metals are employed in the electrical and chemical industries, in dentistry and jewelry, and for numerous miscellaneous purposes. Sales to consumers in the United States were 509,232 ounces in 1943 compared with 375,812 ounces in 1942.

The most widely used metal of the group is platinum, which constituted 344,719 ounces (68 percent) of the total platinum metals sold to consumers in the United States in 1943. The electrical industry, which was a close second to the chemical industry as the chief consumer of platinum in 1942, advanced to first place in 1943 by taking 185,281 ounces (54 percent) of the total platinum sold. The largest outlets for platinum in the electrical industry were for magneto and other contacts and electronic tubes. The chemical industry dropped to second place as a consumer of platinum but accounted for 131,716 ounces (38 percent) of the total sales. The largest outlets for platinum in the chemical industry were as catalysts to produce nitric and sulfuric acids, as spinnerets for glass fiber and rayon, and in laboratory ware. Sales of platinum to the dental industry increased phenomenally and accounted for 27,044 ounces (8 percent) of the total sold. Because of the ban on platinum in jewelry, sales declined to 438 ounces in 1943 (66,518 in 1942).

Next to platinum, palladium is the most extensively used metal of the group; it constituted 137,709 ounces (27 percent) of the total platinum metals sold to domestic consumers in 1943. The jewelry industry—the third largest consumer in 1942—ascended to first place in 1943 and took 45,218 ounces (33 percent) of the total palladium sold. Sales of palladium to the jewelry industry increased 130 percent. The dental industry was the second largest outlet for palladium in 1943, taking 41,522 ounces (30 percent) of the total sold. The electrical industry dropped from first to third place as a consumer of palladium in 1943; it accounted for 25,907 ounces (19 percent) of the total sold. Sales of palladium to the chemical industry gained 158 percent in 1943.

The consumption of the other platinum metals—iridium, rhodium, osmium, and ruthenium—is comparatively small; it made up 5 percent (26,804 ounces) of the total for the group in 1943. Ruthenium and iridium were the most extensively used metals of this group, followed in order by rhodium and osmium. Sales of ruthenium and iridium were 44 and 24 percent, respectively, greater than in 1942, but those of rhodium and osmium declined 38 and 5 percent, respectively.

The following table shows sales of platinum metals by refiners, importers, dealers, and Metals Reserve Co. to consumers in the United States in 1943.

Platinum metals sold to consuming industries in the United States in 1943, in troy ounces

Industry	Platinum	Palladium	Iridium, osmium, rhodium, and ruthenium	Total
Chemical	131,716	14,162	4,154	150,032
Electrical	185,281	25,907	15,851	227,039
Dental	27,044	41,522	160	68,726
Jewelry	438	45,218	2,080	47,736
Miscellaneous and undistributed	240	10,900	4,559	15,699
	344,719	137,709	26,804	509,232

Stocks.—Stocks of platinum metals in all forms in the hands of refiners, importers, and dealers totaled 323,013 ounces on December 31, 1943, compared with 303,387 ounces at the close of 1942.

Stocks of platinum metals held by refiners [1] in the United States, December 31, 1939–43, in troy ounces

Year	Platinum	Palladium	Iridium	Osmium, rhodium, and ruthenium	Total
1939	71,393	29,273	7,000	9,884	117,550
1940 [1]	144,302	93,244	32,368		269,914
1941 [1]	150,887	138,014	33,942		322,843
1942 [1]	160,724	107,383	35,280		303,387
1943 [1]	176,560	104,372	42,081		323,013

[1] In 1940 figures also include stocks held in the United States by importers from the United Kingdom; in 1941, 1942, and 1943 figures also include stocks held in the United States by all importers and dealers.

FOREIGN TRADE [2]

Imports.—Imports of platinum metals into the United States increased for the third successive year to establish a new high; they were 15 percent greater than in 1942, the previous record year. The principal sources of imported platinum metals in 1943 were Canada (263,607 ounces), U. S. S. R. (41,272 ounces), and Colombia (38,232 ounces). Imports of unrefined materials (263,968 ounces) were virtually the same in 1943 as in 1942, but imports of refined metals increased to 98,283 ounces (51,350 ounces in 1942). Imports of palladium, osmium, and ruthenium were about 4½, 2½, and 3 times, respectively, those of 1942, but imports of rhodium were only one-tenth as much.

---

[2] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Platinum metals (unmanufactured) imported for consumption in the United States, 1942–43

Material	1942		1943	
	Troy ounces	Value	Troy ounces	Value
Unrefined materials: [1]				
Ores and concentrates of platinum metals	181, 271	$6, 897, 495	92, 709	$2, 829, 164
Grains and nuggets (including crude, dust, and residues)	68, 187	2, 006, 500	98, 401	2, 884, 542
Sponge and scrap	13, 918	341, 316	72, 783	2, 218, 706
Osmiridium	276	23, 367	75	5, 054
	263, 652	9, 268, 678	263, 968	7, 937, 466
Refined metals:				
Platinum	32, 254	1, 193, 183	41, 272	1, 545, 975
Palladium	9, 984	190, 892	43, 874	932, 392

Ruthenium	3, 504	89, 601	10, 515	293, 693
	51, 350	2, 037, 887	98, 283	2, 998, 777
	315, 002	11, 306, 565	362, 251	10, 936, 243

[1] The concentrates and crude imported from Canada contain platinum, palladium, iridium, rhodium, and ruthenium, and the crude sponge imported from Canada contains platinum and palladium. Although the U. S. Department of Commerce records "platinum content" for these entries, the Bureau of Mines has determined from the importers of these materials that most of the entries reflect the platinum metals content. The Bureau of Mines has also determined from the largest importer of crude platinum from Colombia that the entries for his material, recorded as "platinum content" by the U. S. Department of Commerce, represent the gross weight of the material.

Exports.—Exports of refined platinum metals and alloys (including scrap) decreased to 1,381 ounces in 1943 from 102,461 ounces in 1942; however, the 1942 exports included 97,800 ounces of refined palladium, which were shipped to Canada for storage. Canada and Brazil were the chief foreign markets for platinum metals in 1943.

Platinum and allied metals exported from the United States, 1939–43

[1] Data not available.
[2] Recovered from nickel-copper mattes.
[3] Year ended June 30 of year stated.
[4] Produced from platinum ores.
[5] January to September, inclusive.
[6] Produced from treatment of gold ores on the Rand.
[7] Estimate.
[8] Subject to revision.
[9] New platinum metals recovered in gold and copper refining of domestic materials.

Canada.—Although the Bureau of Mines is not at liberty to publish figures on the recovery of platinum metals from the nickel-copper ores of the Sudbury district, Ontario, in 1943, it can be stated that the output was substantially less than the all-time high in 1942, which was 298,400 ounces of platinum and 226,600 ounces of other platinum-group metals.

Colombia.—Colombia exported 39,961 ounces of crude platinum in 1943 (49,163 in 1942). The South American Gold & Platinum Co. produced 23,945 ounces of crude platinum metals in 1943 (25,786 in 1942) and 55,446 ounces of gold (51,974 in 1942). The figures for other operators are not available.

TITANIUM

By Allan F. Matthews

SUMMARY OUTLINE

	Page		Page
General statement	807	Consumption and uses	811
Domestic production	808	Prices	813
Foreign trade	809	Technology	813
Stocks	811	World production	814

GENERAL STATEMENT

Development of titanium mining on a substantial scale in the United States during 1943 nearly tripled production and supplied fully two-thirds of the domestic ilmenite consumed and one-fourth of the rutile. Imports of ilmenite did not quite fill the supply-demand gap, so stocks were reduced one-fourth. Rutile entries, on the other hand, were ample to maintain stocks, even in the face of increased consumption. Titanium prices were unchanged during 1943.

Post-war demand is expected to be double pre-war consumption, principally because titanium provides a superior white pigment but partly because it is the most abundant ferro-alloy metal and is a standard requirement of the expanded welding-rod industry. The United States probably will achieve self-sufficiency in ilmenite during the latter half of 1944. Largely responsible for that position is the New York ilmenite mine, which is expected to continue operation after the war, although possibly at a reduced rate if it again becomes more economical to import ore from India and other foreign sources.

Creation of a titanium pigment cartel in conspiracy with German, British, Italian, Japanese, and other foreign interests in violation of the Antitrust Act was charged by the Department of Justice in a Federal grand jury indictment in New York City June 28, 1943, and before the War Mobilization Subcommittee, Senate Military Affairs Committee, November 4. E. I. du Pont de Nemours & Co., Inc., the National Lead Co., and several foreign firms were charged with division of the world market into noncompetitive areas, international patent transfers to avoid seizure as enemy property, exorbitant prices, and monopolistic control of the industry in the United States. Replying to the charges, Fletcher W. Rockwell, president of the National Lead Co., stated that they referred to transactions considered legal and proper at the time they were made; he called upon the Government to formulate a policy on the conduct of international business.

DOMESTIC PRODUCTION

Ilmenite production in the United States nearly tripled in 1943 compared with 1942, and rutile output increased 51 percent. Ilmenite concentrates shipped in 1943 contained 44 to 60 percent TiO_2, and rutile concentrates ranged from 90 to 94 percent TiO_2.

Production and mine shipments of titanium concentrates from domestic ores in the United States, 1939–43

Year	Ilmenite				Rutile			
	Production (short tons)	Shipments			Production (short tons)	Shipments		
		Gross weight (short tons)	TiO_2 content (short tons)	Value		Gross weight (short tons)	TiO_2 content (short tons)	Value
1939	14,602	16,872	7,668	$137,042	(1)	(1)	(1)	(1)
1940	20,668	20,702	9,505	183,686	2,888	2,657	2,475	$393.243
1941	23,297	21,526	9,930	196,522	3,130	3,431	3,192	493,782
1942	77,208	93,397	41,328	1,805,823	2,648	2,649	2,466	410,956
1943	203,551	211,715	94,283	3,738,970	3,987	3,941	3,639	610,879

[1] Bureau of Mines not at liberty to publish figures.

Arkansas.—The Titanium Alloy Co. of Arkansas, Inc., subsidiary of Titanium Alloy Manufacturing Co., sold its rutile property at Malvern, Magnet Cove district, Hot Spring County, to the Magnet Cove Rutile Co. early in December 1943. During 21 months of operation the former owner produced 580 short tons of rutile (largely from a stock pile of crude concentrates averaging 52 percent TiO_2 purchased with the property) and shipped 625 tons (45 from stock) averaging 90 percent TiO_2 and valued at $79,500.

Florida.—Riz Mineral Co. operates a concentrator at Melbourne, Brevard County, for the production of rutile, ilmenite, and zircon. The ore feed is sand—formerly from stretches of beaches in the vicinity of Melbourne but now from dunes some 3 miles inland from Vero Beach, Indian River County. In August 1943 Rutile Mining Co. of Florida, subsidiary of Titanium Alloy Manufacturing Co., began to produce rutile and ilmenite from sand dunes about midway between Jacksonville, Duval County, and the Atlantic coast. This company signed a contract with Government-owned Metals Reserve Co. to deliver 2,900 short tons of rutile between June 1943 and April 1944. St. Johns River Lumber & Development Co., St. Augustine, St. Johns County, shipped a small quantity of mixed ilmenite-rutile-zircon concentrate in 1943. In Duval and St. Johns County near Ponte Vedra is a 17-mile beach property which was worked for ilmenite, rutile, zircon, and monazite in 1916–27 by Buckman & Pritchard, Inc., a subsidiary of the National Lead Co. after 1922. Depletion of the best ore and availability of larger and cheaper quantities of ilmenite from abroad led to discontinuance of mining, and the subsidiary (renamed the Ponte Vedra Co.) developed the property residentially and sold it in December 1942.[1] Beach deposits in Santa Rosa, Escambia, and Okaloosa Counties near Pensacola are estimated to contain 750,000 tons of material averaging 1.2 percent kyanite, 1.0 percent ilmenite, 0.4 percent zircon, and 0.1 percent rutile.

---

[1] National Lead Co., 51st Annual Report for Fiscal Year Ended December 31, 1942, pp. 4–5.

New York.—The National Lead Co., Tahawus, Essex County, in 1943 mined 985,261 short tons of ore (16 percent TiO_2 and 33 percent Fe) and concentrated 983,759 tons, which yielded 165,612 tons of ilmenite (165,198 tons were shipped) averaging 44 percent TiO_2 and 398,713 tons of magnetite averaging 56 percent Fe. Shortage of labor and a bottleneck in the crushing plant prevented reaching the goal of 900 short tons of ilmenite daily, a level now expected by mid-1944. Five months operation in 1942 yielded a production of 45,395 short tons of ilmenite and shipments of 43,923 tons. Production technology at the property was described.[2] Ore reserves are estimated at 43 million tons.[3]

North Carolina.—Ilmenite concentrates averaging 50 percent TiO_2 are produced at Finley, Caldwell County, by the Yadkin Valley Ilmenite Co., subsidiary of the Glidden Co. The current output of about 40 tons daily is utilized by the American Zirconium Corporation, St. Helena, Baltimore, Md. (an affiliated company), to make titanium pigments. It is planned as soon as equipment is available to expand the Yadkin Valley operations to possibly 100 tons daily of ilmenite, some of which would be available for sale.

Oregon.—Although chromite was recovered in 1943 from marine black sands of Coos County, the expected ilmenite byproduct did not materialize.

Texas.—A deposit in Jeff Davis County[4] contains a fine-grained rutile disseminated in hard, silicified tuff that can be concentrated to 87 percent TiO_2 with a recovery of 67 percent.[5]

Virginia.—The American Rutile Corporation, subsidiary of the Metal & Thermit Corporation, produces rutile and ilmenite near Roseland, Nelson County. Southern Mineral Products Corporation, subsidiary of the Vanadium Corporation of America, sold its ilmenite property in the same district to Virginia Chemical Corporation, subsidiary of Interchemical Corporation, December 1943.

FOREIGN TRADE[6]

Imports.—Ilmenite imports in 1943 recovered from the slump of 1942, largely as a result of substantially larger shipments from Canada. Receipts from India continued to be small, partly owing to the shortage of barges to move the concentrates from the mines to a point of export. Rutile imports continued to climb in 1943. Australia supplied most of the increase, but Brazil's important contribution was maintained at its 1942 level. Cameroun is becoming a significant source of rutile. Titanium is imported from Australia only in the form of mixed zircon-rutile-ilmenite concentrates, which are separated into their component minerals by the International Titanium Corporation (subsidiary of the American Rutile Corporation and Ventures, Ltd.), Carteret, N. J.; Orefraction, Inc., Pittsburgh, Pa.; and Titanium Alloy Manufacturing Co., Niagara Falls, N. Y. There were no imports of ferrotitanium in 1941–43.

Cameroun (French)[3]				146	1,095
India and Dependencies					818
Portugal		6			
Total as reported	442	156	3,114	6,423	9,635
Australia: In "zirconium ore"[2]	345	2,008	3,177	4,102	4,703
Grand total	787	2,164	6,291	10,525	14,338
Value of "As reported"	$23,170	$14,849	$306,176	$623,917	$823,624

[1] Classified as "ore" by the United States Department of Commerce.

[2] All imports of titanium from Australia in 1939–43 were in mixed zircon-rutile-ilmenite concentrates. Totals of mixed concentrates are derived by addition of the United States Department of Commerce figures for imports of ilmenite, rutile, and "zirconium ore" from Australia. These totals are divided by the Bureau of Mines (on the basis of surveys of importers) into the three component minerals. The excess quantities of ilmenite and rutile over the quantities reported by the United States Department of Commerce in those specific categories are entered as "In 'zirconium ore.'"

[3] Includes quantities reported by the United States Department of Commerce as originating in French Equatorial Africa, from which no rutile production has been recorded.

Exports.—Titanium products valued at 2¼ million dollars were exported in 1943. Most of the concentrates (probably rutile) and alloys went to Canada. Of the pigments, 86 percent went to Canada, and 7 percent was divided about equally between Argentina and Brazil. The quantity of tetrachloride exported was 694 tons—43 percent to United Kingdom, 27 percent to Egypt, 18 percent to India, 11 percent to Algeria, and 1 percent to other countries.

Exports of titanium products from the United States, 1939–43, by classes

Year	Concentrates		Metal and alloys (including ferro-alloys)		Dioxide and pigments		Tetrachloride and other compounds	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1939	(1)	(1)	(1)	(1)	4,319	$698,063	(1)	(1)
1940	(1)	(1)	(1)	(1)	4,962	867,535	(1)	(1)
1941	[2] 432	[2] $70,613	[2] 150	[2] $35,687	7,821	1,609,071	[3] 17	[3] $5,792
1942	618	117,886	461	60,938	8,870	1,707,433	24	13,666
1943	576	103,947	760	117,402	9,765	1,830,344	728	442,591

[1] Data not available.

[2] Data cover last 6 months only.

[3] Data cover last 4 months only.

STOCKS

Ilmenite stocks continued to decline during 1943, but they constituted a 5 months' supply, even at the end of the year. Rutile stocks were little changed.

Stocks of titanium concentrates in the United States at end of year, 1942–43, in short tons

Stocks	1942				1943			
	Ilmenite		Rutile[1]		Ilmenite		Rutile	
	Gross weight	Estimated TiO_2 content	Gross weight	Estimated TiO_2 content	Gross weight	Estimated TiO_2 content	Gross weight	Estimated TiO_2 content

Distributors[2]	11,541	5,371	1,778	1,653	7,808	3,514	949	883
Consumers	149,153	81,735	1,906	1,775	118,263	57,786	1,871	1,745
Government			2,194	2,062			3,253	3,058
Total stocks	172,611	92,248	5,932	5,540	129,824	63,071	6,173	5,780

[1] Revised.

[2] Includes ilmenite and rutile content of mixed zirconium-titanium concentrates.

CONSUMPTION AND USES

Consumption of ilmenite advanced 18 percent in 1943 compared with 1942, but the increase served little more than to compensate for use of lower-grade domestic ores. Ilmenite was used principally in pigments (96 percent) and alloys (3 percent). Rutile consumption spurted 66 percent, and the applications were welding-rod coatings (70 percent) and alloys (over 29 percent).

Consumption of ilmenite and rutile in the United States, 1942–43, by products, in short tons

Product	Ilmenite		Rutile	
	Gross weight	Estimated TiO_2 content	Gross weight	Estimated TiO_2 content
1942				
Pigments (manufactured titanium dioxide)[1] [2]	244,465	134,964		
Welding-rod coatings[1]	56	28	8,857	8,326
Alloys and carbide	11,802	5,899	1,652	1,526
Ceramics			92	86
Miscellaneous[3]	1,212	521	15	14
Total consumption	257,535	141,412	10,616	9.952
1943				
Pigments (manufactured titanium dioxide)[1]	290,573	137,399		
Welding-rod coatings[1]	194	113	12,358	11,617
Alloys and carbide	10,583	4,546	5,221	4,782
Ceramics			21	20
Miscellaneous[3]	1,472	810	34	32
Total consumption	302,822	142,868	17,634	16,451

[1] "Pigments" include all manufactured titanium dioxide, consumption of which in welding-rod coatings was 4,900 tons in 1942, and 5,700 in 1943.

[2] Partly estimated.

[3] Consists of ilmenite used as a steel flux and rutile used in lamp-electrode coatings and as a steel deoxidizer.

Titanium pigments.—Production of titanium pigments in 1943 was somewhat less than in 1941–42, but sales were greater than in any year except the 1941 peak. The output was approximately three-quarters of capacity, largely because of reductions in the quantity and grade of ilmenite procured. On the other hand, demand greatly exceeded capacity. Government control of distribution was strengthened December 6, 1943 (Order M–353), amended December 24 to include extended pigments containing over 12 percent TiO_2. Titanium dioxide production technology, a comparison of anatase- and rutile-type pigments, and the causes of chalking were described comprehensively.[7] Rutile-type pigments (made from ilmenite but possessing the crystal structure of rutile) have been commercially available only about 3 years and the chalk-resistant type for only 2 years, but already their use is mandatory in a number of Government specifications.[8] Titanium paints such as Ti-Pure and Titanox are noted for covering power, whiteness, and durability and enjoy a greater volume of business than any other white paint. Paper manufacturers have greatly increased their demands for titanium dioxide, a pulp extender that enables reductions as great as 50 percent in paper weight with no loss in opacity.

Welding-rod coatings.—About 481,000 short tons of titanium-coated welding rods were produced in the United States in 1943 compared with 321,000 tons in 1942 and 152,000 tons in 1941. Titanium shields the arc from oxidation during welding and produces a brittle slag that protects the cooling weld deposit.[9] Welding has replaced riveting in much military construction; for example, a Liberty ship uses some 250,000 linear feet of welding in place of 1,000,000 rivets.[10]

Titanium alloys.—Ferrocarbontitanium (15–20 percent Ti, 3–8 percent C) improves the rimming action of steel to be rolled and acts as a deoxidizer in killed steel. Ferrotitanium (18–45 percent Ti, 0.1 percent C max.) prevents intercrystalline embrittlement and weld decay in stainless steel, inhibits brittleness of 5-percent chromium steel, and increases the hardenability of forging steel.[11] Additions of 0.1–0.3 percent Ti to aluminum alloys refine the grain.[12] A titanium predip before phosphoric treatment of surfaces to be zinc plated has been recommended.[13] Titanium-zinc alloys were investigated.[14] Pure titanium metal is used in radio tubes. Titanium carbide is a constituent of hard cutting alloys for machine tools.

Other uses of titanium.—Some steel companies are using 1 part of ilmenite to replace 1 to 4 parts of fluorspar as a flux in making titanium-bearing stainless steel.[15] Titanium tetrachloride, ordinarily made from rutile, is used by the United States Navy to produce smoke screens.

PRICES

No price changes affected any form of titanium in 1943. Ilmenite and rutile prices were fixed by the Office of Price Administration February 22, 1943 (Regulation 327), at levels prevailing in March 1942. Ilmenite, 60 percent TiO_2, was nominally quoted at $28–$30 a long ton, f. o. b. Atlantic seaboard, and rutile, 94 percent TiO_2, at 8–10 cents a pound. Steel quoted ferrotitanium, ton lots, at $1.23 per pound of contained Ti for 40- to 45-percent grade and $1.35 for 20- to 25-percent grade; and ferrocarbontitanium, 15–20 percent Ti, at $142.50 a short ton for 6- to 8-percent carbon and $157.50 for 3- to 5-percent carbon. Titanium metal, 96–98 percent, was listed at $5–$5.50 a pound. The base price of manufactured titanium dioxide remained fixed at 14½–16½ cents a pound.

TECHNOLOGY

Types of dynamite stronger and faster than customarily employed are necessary in blasting the dense, tough titanium ore at Tahawus, N. Y.[16] A feature of the mill at that property is a new type of classifier which provides accurate hydraulic sizing of the table feed.[17] The grinding characteristics of rutile have been compared with those of other minerals.[18]

Concentration of a Caldwell County (N. C.) titanium ore containing nearly 70 percent ilmenite, no rutile or magnetite, and a gangue of sericite talc was undertaken on a laboratory scale. The ore, averaging 41 percent TiO_2 and 33 percent FeO, was ground to 80-mesh and concentrated by froth flotation to a product analyzing 54 percent TiO_2 and 39 percent FeO. Methods using either fatty acid-alkali or amine acid reagents appear equally satisfactory. The indicated recovery of ilmenite was 80 percent, which could possibly be improved by re-treatment of middling products. The reagent cost is estimated at not over 12 cents per ton of ore treated.[19]

Titanium ores can be reduced by charging them into an electric furnace with ordinary clay and off-grade coke breeze.[20] If titaniferous magnetite is reduced to sponge iron under conditions not permitting reduction of titanium compounds, the sponge iron can be melted with additions of lime and carbon to yield a highly concentrated titanium slag.[21] Titanium tetrachloride (a smoke-screen chemical) can be produced by treating titanium-bearing clay with carbonyl chloride at 350°–400° C., according to a German patent.[22] Titanium is one of the most hazardous of 14 metal powders tested.[23] Metal Hydrides, Inc., Beverly, Mass., has established a fellowship at Boston University for research on the properties and utilization of titanium hydride.[24]

[1] Data not available.
[2] Subject to revision.
[3] Includes 26 tons of garnet-ilmenite.
[4] January to September, inclusive.
[5] Bureau of Mines not at liberty to publish figures.
[6] In addition, zircon-rutile-ilmenite concentrates were produced as follows—1937: 73 tons; 1938: 98 tons.
[7] Less than 1 ton.
[8] Exports.

Australia.—The bulk of the Australian titanium output is in the form of mixed zircon, rutile, and ilmenite mined and concentrated on the beaches of New South Wales and shipped to the United States for separation and consumption. The deposits are estimated to contain a million tons of mixed concentrates.[25] One of the companies—Metal Recoveries Pty., Ltd., New Brighton, a subsidiary of International Titanium Co.—produces monthly[26] concentrates containing about 78 tons of rutile.

Brazil.—Deposits of titanium ore in Brazil were described.[27] From its three properties in the municipality of Guarapary, Espirito Santo, the Soc. Monazita e Ilmenita do Brasil, Ltda., principal producer of ilmenite, mined 3,033 metric tons in 1942 compared with 3,939 tons in 1941 and 611 tons in 1940.

Ceylon.—Between 3 and 4 million tons of ilmenite containing 60–62 percent TiO_2 occur in beach sands in northern Ceylon, and an equal quantity is distributed in leaner sands along the eastern and western coasts. Zircon and monazite are associated minerals.[28]

---

[26] Northern Miner, vol. 29, No. 9, May 20, 1943, p. 3.
[27] Miranda, Jose, Areias ilmeniticas no Brasil: Mineracão e Metalurgia, vol. 7, No. 40, September–October 1943, pp. 195–198. Francesconi, Octacilio, Rutilo no Ceara: pp. 207–208.

French West Africa.—Ilmenite is produced near Rufisque and at the mouth of the Casamance River, Senegal. Exploitable deposits of rutile occur in the vicinity of Kouande, Dahomey.

India.—American ships delivering war supplies to India were expected to bring back large quantities of ilmenite in 1943, but there was a scarcity of barges to bring the concentrates from the beaches to the shipping port of Cochin. A pilot plant for making titanium dioxide is in operation in India.[29]

Portugal.—Exports of ilmenite were 1,510 metric tons from the Portuguese American Co. to the United Kingdom in 1942.[30]

Spain.—Titanium deposits are being worked by Industria Titán, S. A., of Barcelona and Sociedad Titania, S. A., of Galicia. Titaniferous magnetite has been found in the Pyrenean foothills near Olot, District of Barcelona, and ilmenite sands along the Sil River District of Galicia. These ores have a TiO_2 content of about 20–25 percent.[31]

Sweden.—The possibility of obtaining titanium as a byproduct of the State shale-oil industry is under investigation.[32]

Union of South Africa.—Sands along parts of the Natal coast, notably at Durban, contain as much as 85 percent ilmenite and 8 percent zircon. Electromagnetic separation has yielded a product analyzing 93 percent ilmenite.[33]

United Kingdom.—Indian ilmenite, 52–54 percent TiO_2, was quoted by Metal Bulletin at 30 s. per long ton, f. a. s., at the end of 1943. Prices of rutile, f. o. b. consumers' works, remained fixed throughout the year at £54 a long ton for Cameroun concentrates, £42–£50 for Indian concentrates, and £45 for Australian concentrates. Ferrotitanium, the demand for which has broadened,[34] cost £100 a long ton for the 2- to 3-percent-carbon grade (20 to 25 percent Ti) and 1 s. 3½ d. per pound for the carbon-free grade. The British Board of Trade planned an inquiry into the titanium pigment cartel allegations by the United States Department of Justice against Imperial Chemical Industries.[35]

BARIUM AND STRONTIUM

Several thousand pounds of barium metal are produced annually from purchased oxide by Kemet Laboratories Co., Inc. (unit of Union Carbide & Carbon Corporation), Cleveland, Ohio, and King Laboratories, Inc., Syracuse, N. Y. These companies and the Hugh S. Cooper Metallurgical Laboratory, Cleveland, Ohio, produce strontium metal. Barium metal is worth \$5–\$8 a pound and strontium metal \$15–\$20 a pound. These alkaline-earth metals, alloyed with aluminum and magnesium, are used as getters in tubes for radios and other electronic devices.[1] A getter is a material placed inside a tube to absorb residual gases and thus maintain a vacuum.

Barium and strontium minerals are discussed in both the Barite, Witherite, and Barium Chemicals chapter and the Minor Nonmetals chapter of this volume.

BERYLLIUM

General statement.—Beryl production in the United States increased 40 percent in 1943 compared with 1942 but constituted only 7 percent of the new supply. The combination of high shipping priority on imports (some by airplane) and of strict use conservation enabled the beryl supply to meet demand and also approximately to double inventories. Beryllium-copper master-alloy shipments reached a record high in the first half of 1943 but declined 19 percent in the second half—principally because of cut-backs in military demand and the desire of fabricators to reduce their stocks. The surplus was not taken up by marginal military and civilian uses because satisfactory substitutes had been developed and reversion to beryllium-copper would entail increased cost in materials and redesigning, according to the War Production Board. Furthermore, marginal users had no assurance that beryllium would not again become so scarce as to deny them access to supplies.

---

[1] Light Metals (London), Gettering and Getters: Vol. 7, No. 73, February 1944, pp. 77–94.

Beryllium in all forms was placed under allocation by the War Production Board June 1, 1942 (Order M–160). The order was amended December 16, 1943, to change allocation from a monthly to a quarterly basis and to exempt from control sales of material containing 2 pounds or less of beryllium.

Domestic mine production.—Domestic mine shipments increased 40 percent in 1943 compared with 1942 to establish another record. Practically the entire output is a byproduct of feldspar, mica, and other pegmatite minerals. The deposit of helvite (sulfosilicate of manganese, iron, and beryllium) at Iron Mountain, Sierra and Socorro Counties, N. Mex., has not been developed because further exploration indicated smaller reserves than expected and because concentration of the ore presented difficulties. A reportedly large find of beryllium in Jackson County, Oreg., proved to be nonexistent.[2] The Bureau of Mines and Geological Survey continued to examine deposits in New England, the Appalachians, Black Hills, and Rocky Mountains.

Beryllium ore shipped from mines in the United States, 1937–43, by States, in short tons

	1937	1938	1939	1940	1941	1942	1943
Colorado	(1)	--------	(1)	(1)	--------	3	68
Maine	(1)	25	(1)	(1)	(1)	45	2
New Hampshire	--------	--------	--------	--------	(1)	16	42

Domestic refinery production.—The Bureau of Mines is not at liberty to release production data on beryllium products, but an idea of the size of the recently expanded industry can be obtained from a statement by the National Research Council[3] that the annual rate of output in early 1943 was 3,000,000 pounds of beryllium-copper master alloy (4 percent Be) and 10,000 pounds of beryllium oxide for phosphorescent lamps; consumption of beryl was stated to be about 7 tons daily. Beryllium-copper master alloy is made by the Beryllium Corporation of Pennsylvania, Reading, Pa., and by Brush Beryllium Co., Cleveland, Ohio. The latter company also produces metal and compounds. Clifton Products, Inc., Painesville, Ohio, a producer of oxide, began making metal in late 1943 and is expected to begin beryllium-copper output in 1944.

Foreign trade.—Beryl imports more than doubled in 1943 compared with 1942, and every inhabited continent contributed to the supply. Exports in 1943 comprised 4,903 pounds of beryllium ore, 54,990 pounds ($49,867) of alloys and metal, and 3,915 pounds ($14,730) of compounds.

Beryllium ore imported for consumption in the United States, 1939–43, by countries, in short tons

Country	1939	1940	1941	1942	1943
Argentina	384	422	861	703	1,162
Australia					457
Brazil	75	377	1,805	912	2,551
India and Dependencies				397	509
Madagascar					74
Portugal					1
Union of South Africa		6		38	86
Total:					
Short tons	459	[1] 805	2,666	2,050	4,840
Value	$14,574	$23,865	$143,992	$137,597	$377,726
Average per ton	$31.75	$29.65	$54.01	$67.12	$78.04

[1] Five tons in addition from Mozambique were reported to the Bureau of Mines.

Stocks.—Inventories of beryl held by the principal miners, dealers and consumers in 1943 declined from 1,400 short tons on January 1 to 1,100 tons on December 31. However, Government-owned Metals Reserve Co. increased its stocks from 725 tons to 2,513 during the year.

Prices.—Domestic beryl, 10–12 percent BeO, was priced at $83–$100 a short ton ($8.33 per unit) in the first 4 months of 1943 and $120–$144 a ton ($12 per unit) during the remainder of the year. Beryllium-copper master-alloy was quoted at $15–$17 a pound.

Uses.—The principal application of beryllium is in beryllium-copper alloys (0.1–3.5 percent Be; 0–2.6 percent Co, Cr, or Ag; remainder Cu), described by the National Academy of Sciences [4] as follows:

> Beryllium-copper is heat treatable to produce the strongest copper-base alloy. Extensive studies have been carried out in various laboratories in endeavors to broaden the use of beryllium-copper alloys and to take advantage of their valuable properties of high fatigue strength; elastic limit and hardness; relatively high tensile strength and electrical conductivity; excellent corrosion resistance; good wear resistance; good resistance to galling against steel and good resistance to room temperature creep (elastic drift); and various fabrication advantages associated with heat treatment or precipitation hardening.
>
> There can be no doubt as to the relative superiority of this alloy for many important applications in both the peacetime and the wartime economy. At the present time beryllium-copper is being used in parts of aircraft, ships, tanks, guns, shells, instruments, engines, motors, radio, telephones, telegraph, tools, and electrical control equipment for machinery and fire protection. In many cases, where small parts are involved, design factors explain the use of this alloy. Thus, in many aircraft instruments, beryllium-copper is used because its properties make possible the use of a smaller part than would be necessary if other materials were used.

Beryllium oxide is used in fluorescent lamps as a white phosphor, in spark plugs and other refractories, and in experimental glasses.[5] Beryllium metal is fabricated into windows for X-ray tubes,[6] and small quantities (0.0001–0.001 percent Be) are added to aluminum-magnesium castings and extrusions. Platinum metals can be conserved by fractional beryllium additions.[7]

Technologic developments.—The Bureau of Mines conducted numerous experiments on the concentration and analysis of beryllium ores in 1943, and publication of results is expected soon. Spot tests[8] and spectrographic methods[9] of detecting beryllium were described. Recent patents give clues to present refining processes.[10] Heat treating of beryllium-copper was studied further.[11] Investigations by the Public Health Service indicate that beryllium is not toxic,[12] but a refiner questions such a conclusion.

Foreign production.—Argentine beryl production in 1942 was from the Provinces of Córdoba (848 metric tons), San Luis (74 tons), and Catamarca (3 tons); future output is expected to decline. The refining plant at Juan Ortiz is not in operation. The Australian production is primarily from the Wodgina tantalite district of Western Australia and the Brazilian output from the States of Paraiba and Rio Grande do Norte. Madagascar ships beryl from the Fianarantsoa mine, about 100 miles inland by rail from the port of Manakara. South-West Africa exported 77 metric tons of beryl to the United Kingdom in 1942. The chief source of beryl in the Soviet Union is the Sherlova Gora mine (latitude 52°33′ N., longitude 116° 15′ E.) in Transbaikal, although there are at least 25 other promising deposits in the country.

World production of beryllium ore, 1937–43, by countries, in metric tons[1]

Country	1937	1938	1939	1940	1941	1942	1943

[1] In addition to countries listed beryllium ore may also be produced in France, Italy, Kenya, Norway, Portuguese East Africa, Rumania, and U. S. S. R. Canada has produced beryl but has sold none.
[2] Estimate based upon United States imports.
[3] South Australia only.
[4] Data not available.
[5] Exports; subject to revision.
[6] January to September, inclusive.

BORON

Production.—Ferroboron (3–18 percent B) production in the United States was 190 short tons containing 15 tons of boron in 1942, and producers' shipments were 113 tons. Corresponding figures for 1943 are not yet available. The producers of ferroboron are Electro Metallurgical Co., Molybdenum Corporation of America, and Ohio Ferro-Alloys Corporation. In addition, complex alloys (0.1–1.9 percent B), such as Bortam, Carbortam, Grainal, Silcaz, and Silvaz are produced by the Electro Metallurgical Co., Titanium Alloy Manufacturing Co., and Vanadium Corporation of America. Amorphous boron, manganese-boron, and nickel-boron are now marketed. Mineral sources and salts of boron are discussed in the Magnesium Compounds and Miscellaneous Salines chapter of this volume.

Uses in steel.—Additions of 0.001 to 0.003 percent (one-third ounce per ton) of boron to steel promote an increase in hardenability (depth of hardness) comparable to that obtained by much larger quantities of the common alloying elements.[13] For example, treatment of a medium-carbon steel with boron alloy increases hardenability about as much as raising the manganese content 0.7 percent, raising the silicon content 1.6 percent, or adding 0.20–0.25 percent molybdenum; furthermore, the boron steel is tougher, at least as ductile, and practically as strong as a similar untreated steel with 0.25 percent molybdenum, and the heats are more uniform.[14] Machinability of fine-grained steels is said to be improved by boron. Although particularly effective in pearlitic manganese steel, boron makes a carbon steel equivalent to a low-alloy steel in hardenability and mechanical properties and makes a low-alloy steel equivalent to a high-alloy steel.[15] Boron is economical to use [16] and conserves strategic ferroalloy metals. Additions must be made to a completely deoxidized steel bath, or the boron must be protected by strong deoxidizers until dissolved. Methods of measuring small quantities of boron have been developed.[17]

Other metallurgical uses.—In cast iron 0.001 percent of boron considerably shortens the annealing cycle,[18] and 0.02–0.12 percent reportedly increases hardness and refines the grain. Boron controls the depth of chill in iron rolls for the steel industry. Chromium-boron is a hard-facing alloy overlayed on shovel tips, clutch fingers, and other abraded surfaces. Boron alloys make efficient resistor elements.[19]

Prices.—Ferroboron, 17.5 percent B, carlots, was quoted at $1.25 a pound in 1943, according to Iron Age.

CALCIUM

Calcium metal is produced on a tonnage scale by the Electro Metallurgical Co. at its Sault Ste. Marie (Mich.) plant. Shipments were placed under allocation control by the War Production Board informally at the beginning of 1943 and officially April 1 (Order M–303), but the balancing of supply and demand permitted suspension of the order August 18, 1943. Calcium metal, 97–98 percent, ton lots, continued to be quoted at $1.25 a pound throughout 1943.

According to Canadian Metals & Metallurgical Industries, calcium-silicon, ton lots, was 16½ cents a pound, f. o. b. Welland, Ontario. Calcium metal and alloys are used primarily in deoxidizing and scavenging steel.[20] Calcium lead (0.1–0.4 percent Ca) [21] is made into cable sheaths, storage-battery grids, and bearings.[22] Calcium improves the grain structure, workability, and corrosion resistance of magnesium alloys.[23]

Calcium metal and calcium-silicon imported for consumption in the United States, 1939–43

Commodity	1939		1940		1941		1942		1943	
	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value	Pounds	Value
Calcium metal	41,718	$17,758	11,900	$6,518	--------	--------	--------	--------	--------	--------
Calcium-silicon	3,972,571	225,312	2,131,758	154,424	111,994	$8,337	60,300	$10,144	--------	--------

CERIUM AND OTHER RARE-EARTH METALS

Cerium master alloy (misch metal) production in the United States was 212,379 pounds in 1943, according to the War Production Board. The producers were Cerium Metals Corporation, Niagara Falls, N. Y.; Kent Metal & Chemical Works, Edgewater, N. J.; and New Process Metals Corporation, Newark, N. J. A typical composition of the master alloy is 52 percent cerium, 22 percent lanthanum, 15 percent neodymium, 7 percent other rare-earth metals (praseodymium, samarium, yttrium, and terbium), and 4 percent iron.[24] The master alloy is diluted to 20–35 percent iron content; and a few percent of boron, silicon, calcium, or other metal is added for special effects, in making ferrocerium for sparking "flints" of cigarette lighters, miners' lamps, and acetylene-welding torches. Small quantities of cerium metal are used in radio tubes and nonferrous alloys. Magnesium alloys usable at higher temperatures than now possible can be developed by additions of cerium.[25]

Imports of cerium alloys from Canada, only foreign source since the outbreak of war, totaled 5,720 pounds ($27,589) in 1943 compared with 11,573 pounds ($65,549) in 1942. Imports of cerium compounds were 119 pounds ($304) in 1943. Exports of cerium alloys and metal were 54,797 pounds ($148,891) in 1943 compared with 26,016 pounds ($84,739) in 1942. The Canadian producer is Shawinigan Chemicals, Ltd., Shawinigan Falls, Quebec. Misch metal (52 percent Ce) is quoted by Metal Bulletin (London) at 35 s. a pound and cerium metal at £7 5 s. a pound. Ferrocerium production was begun in Australia from local ores.[26]

The principal ore of cerium is monazite,[27] described in the Minor Nonmetals chapter of this volume.

CESIUM AND RUBIDIUM

Cesium metal and salts and rubidium salts are produced by the Maywood Chemical Works, Maywood, N. J., from pollucite it extracts at the Tin Mountain mine, 7 miles west of Custer, Custer County, S. Dak. Cesium salts are produced by the Foote Mineral Co., Philadelphia, Pa. Occurrences of cesium and rubidium in New England were recently described.[28] Efforts were being made in May 1944 to import several tons of pollucite from the Union of South Africa. Cesium metal (100 percent Cs, 100-gram lots) was quoted at $4 a gram and the salts of cesium and rubidium at 15–50 cents a gram in September 1943, according to Maywood Chemical Works. Small quantities of cesium and rubidium are used in photoelectric cells and radio tubes. Important quantities of these metals have been discovered in the Boliden mines at Varutrask, Sweden.

COLUMBIUM AND TANTALUM

Tantalum, placed under allocation control by the War Production Board, May 22, 1942 (Order M–156), has been one of the most critical metals of World War II. Two-thirds of the tantalite imports and some of the columbite arrived via airplane in 1943. Ferrocolumbium allocation began March 25, 1943 (Order M–296). In contrast to the gradual easing of supply of most other ferroalloys, the use of ferrocolumbium was restricted in December to those applications in aircraft construction in which ferrotitanium or other materials have proved ineffective.

Domestic production.—Columbium-ore shipments in 1943 included 2,970 pounds from the McKinney mines of the Carolina Mineral Co. and Whitehall Co., Inc., Spruce Pine area, Mitchell County, N. C., and 615 pounds from Robert A. Shipley, Canon City, Fremont County, Colo. Tantalum-ore shipments by Arthur Montgomery, Harding mine, Dixon, Taos County, N. Mex., comprised 6,137 pounds of microlite (71 percent Ta_2O_5, 6 percent Cb_2O_5), 1,075 pounds of microlite (65 percent Ta_2O_5, 9 percent Cb_2O_5), and 464 pounds of tantalite (43 percent Ta_2O_5, 36 percent Cb_2O_5).

Columbium and tantalum ores shipped from mines in the United States, 1938–43, by States

1943	1,000	7,676		735		9,411	27,621

---

[28] Hess, Frank L., Whitney, Roscoe J., Trefethen, Joseph, and Slavin, Morris, The Rare Alkalis in New England: Bureau of Mines Inf. Circ. 7232, 1943, 51 pp.

Ferrocolumbium is produced by the Electro Metallurgical Co., Niagara Falls, N. Y., and tantalum metal by the Fansteel Metallurgical Corporation, North Chicago, Ill. Part of the output of the latter company is in the Government-owned Tantalum Defense Corporation plant, for which the Defense Plant Corporation, subsidiary of the Reconstruction Finance Corporation, provided $5,350,000.

Foreign trade.—Imports are shown in the following table. Exports in 1943 comprised 27 pounds ($37) of ferrocolumbium and 184 pounds ($15,447) of tantalum metal and alloys. There were no exports of tantalum ore or compounds.

Columbium and tantalum ores imported for consumption in the United States, 1941–43, by countries, in pounds

Country	Columbium ore			Tantalum ore		
	1941	1942 •	1943	1941	1942	1943
Argentina	2,914		2,685			2,420
Australia				29,574	[1] 1,470	10,708
Belgian Congo		36,422		146,904	309,843	157,073
Brazil	2,229	1,133		161,996	237,210	416,874
India and Dependencies			21,600			1,805
Mozambique						3,567
Nigeria	1,435,312	1,724,800	2,350,329			5,757

Total: Pounds	1,440,455	1,762,355	2,382,050	403,464	567,494	643,080
Value	$504,537	$608,917	$844,544	$188,936	$467,418	$724,066

[1] Classified by U. S. Department of Commerce as from New Zealand, which has no recorded production.

Stocks.—The Government stock pile held by the Metals Reserve Co. (or its agent, the Colonial Mica Co.) included 11,371 pounds of columbite, 1,050 short tons of columbite-bearing slag, and 376,441 pounds of tantalite at the end of 1943. This compares with a Government inventory of no columbite and 427,756 pounds of tantalite at the end of 1942.

Prices.—Government-owned Metals Reserve Co. began May 1, 1943, purchasing columbium ore (minimum 50 percent Cb_2O_5 and not more than 7.5 percent TiO_2 or 5 percent SnO_2) at 25 cents a pound (gross weight, no payment for Ta_2O_5 content); and tantalum ore (minimum 40 percent Ta_2O_5 and not more than 3 percent TiO_2 or 3 percent SnO_2) at $1.75 per pound of contained Ta_2O_5 for 40-percent material, $2.25 for 50-percent, $2.75 for 60-percent, and $3.25 for 70-percent material. E&MJ Metal and Mineral Markets continued to quote ferrocolumbium, 50–55 percent Cb, at $2.25–$2.30 per pound of contained Cb; columbium metal at $500–$560 per kilogram ($227–$254 per pound); and tantalum metal at $143–$160.60 per kilogram ($65–$73 per pound).

Uses.—Corrosion-resistant steels containing 0.5–0.8 percent columbium are used in aircraft exhaust systems,[29] supercharger systems, and engine parts exposed to temperatures exceeding 800° F. and subject to severe corrosion or conditions likely to result in fatigue failures. Half of the tantalum consumed in 1943 was for radio and other electronic tubes. One manufacturer (Westinghouse Lamp Division) stated in the fall of 1943 that its tube production was 11 times as great as 2 years ago. Potassium-tantalum fluoride is a catalyst for butadiene synthetic rubber, tantalum carbide a component of cutting tools, and tantalum oxide a constituent of silicaless glass for aerial camera lenses. Among the most corrosion-resistant metals, tantalum is used in chemical equipment and in skull plates and other surgical applications.[30]

---

[29] Campbell, H. A., Stainless Steel Aircraft Exhausts: Iron Age, vol. 151, No. 25, June 24, 1943, pp. 56–58.

Foreign production.—The Jantar Nigeria Co., Ltd., produced about 500 metric tons of columbite in the year ended September 30, 1943.[31] Prospecting and developing columbite and tantalite deposits in Nigeria has been placed under Government license control.[32] Argentina produced 5 metric tons of columbium-tantalum ore in 1942. Columbite was discovered in British Guiana. Brazil exported 180.8 metric tons of tantalite in 1943—all to the United States. The Brazilian deposits were described comprehensively.[33] Belgian Congo output of tantalite, largely by the Geomines group, is reported tentatively at 160 metric tons in 1943. Tantalum has been discovered at Sproul Lake, 35 miles northeast of Yellowknife, Northwest Territories, Canada.[34]

GERMANIUM

Small quantities of germanium metal, oxide, and chloride were produced by the Eagle-Picher Lead Co., Joplin, Mo., in 1943. Cadmium flue dust generally contains germanium, but no demand has yet developed that is sufficient to warrant systematic production. Germanium is a catalyst in the hydrogenation of coal.[35] The metal is quoted at 19s. 6d. per gram and the oxide at 15s. for 99.5-percent and 22s. 6d. for 100-percent, according to the Metal Bulletin.

INDIUM

Domestic production.—Indium-metal production in the United States in 1943 increased more than a third over 1942. The Bureau of Mines is not at liberty to publish production figures, but the Wall Street Journal stated that the indium output was about 65,000 troy ounces in 1942.[36] Sales of indium metal and salts tripled in 1942 compared with 1941 and nearly tripled again in 1943, according to a brochure of the Indium Corporation of America, Utica, N. Y., principal distributor of indium and a subsidiary of Anaconda Copper Mining Co. and Oneida, Ltd. (silverware manufacturer). Indium output—a byproduct of zinc and lead operations—is made predominantly by the Anaconda Copper Mining Co. but also by the American Metal Co., Ltd., American Smelting & Refining Co., and National Zinc Co.,

Inc. A few grams were recovered upon a laboratory basis by Eagle-Picher Mining & Smelting Co. and the Sherwin-Williams Co. in 1943.

Prices.—The price of indium metal, 99 percent, was $10 per troy ounce during 1943 and until March 14, 1944, when the price of metal, now listed as 99.9 percent, was reduced to $7.50–$8.50, according to E&MJ Metal and Mineral Markets.

Uses.—Indium coatings increase the resistance of aircraft-engine bearings to corrosion and wear under severe operating conditions, and this application absorbed almost all of the metal consumed in 1943. Small quantities of indium were used for decorative plating and solders. Indium-zinc coatings have proved satisfactory for airplane hollow-steel propeller blades. Indium-zinc [37] and indium-gold [38] alloys have been described, and an annotated bibliography of indium has been published.[39]

Foreign production.—Consolidated Mining & Smelting Co. of Canada, Ltd., Trail, British Columbia, produced 471 troy ounces of indium in 1942 and none in 1943. Sphalerite specimens from British Columbia and Germany and stannite samples from British Columbia and Bolivia were found spectrographically to contain at least 0.1 percent In.[40]

LITHIUM

Lithium metal is produced by Lithaloys Corporation, New York, N. Y., and Maywood Chemical Works, Maywood, N. J. It is added to copper-base alloy melts as a scavenger and is a minor constituent of certain nonferrous alloys. Lithium metal, 98–99 percent, 100-pound lots, was quoted at $15 a pound throughout 1942, according to E&MJ Metal and Mineral Markets.

Ores and compounds of lithium are discussed in the Minor Nonmetals chapter of this volume.

RADIUM AND URANIUM

Radium was in strong demand during 1943, notwithstanding certain trade-journal comments to the contrary. The uranium industry was greatly stimulated by a Government program having materials priority over all other military procurement, but most of the facts were buried in War Department secrecy.

Domestic production.—Radium and uranium are produced as an accessory of vanadium from carnotite ores mined in Arizona, Colorado, and Utah, but figures are not available for publication at this time.

Foreign trade.—Radium imports reached a record high in 1943. All the radium, mesothorium, and uranium imported in 1942–43 came from Canada, except entries of 100 milligrams of radium from Belgium (originally) and 525,559 pounds of uranium ore from Belgian Congo in 1942. Exports in 1943 comprised 82 milligrams ($1,610) of radium, 2,571 milligrams of radium compounds ($65,937), 865 milligrams of mesothorium ($20,758), and 145,613 grams ($1,972) of uranium compounds.

Radium salts, radioactive substitutes, and uranium ore and compounds imported for consumption in the United States, 1939–43

Year	Radium salts			Radioactive substitutes [1] (value)	Uranium ore		Uranium oxide and salts	
	Grams	Value						
		Total	Average per gram		Pounds	Value	Pounds	Value
1939	78.631	$1,953,820	$24,800	$966	5	$10	1,439,324	$1,197,786
1940	30.311	748,097	24,700	5,650	2,400,198	2,110,927	240,199	388,355
1941	4.412	110,202	25,000	13	----------	----------	387,505	501,370
1942	23.043	377,326	16,400	50	541,307	806,919	377,398	851,098
1943	90.755	1,366,538	15,100	35,589	----------	----------	211,348	413,410

[1] Principally mesothorium.

Prices.—Radium was nominally quoted at $25 a milligram during 1943, but actual sales probably averaged lower. Orange or yellow sodium uranate remained at $1.65 a pound, and black uranium oxide was not quotable, according to Glass Industry.

Uses of radium.—Radium is considered one of the most effective weapons in combatting cancer, although it now shares popularity with newer therapeutic agents, for example, high-voltage X-rays and artificially radioactivated elements. About 157 grams of radium were in medical use in the United States in 1939, according to the National Cancer Institute, Public Health Service. Dial painting of aircraft and ship-instrument panels, military ground-direction markers, compasses, watches, gun sights, and other instruments consumed approximately 75 grams of radium in 1943 compared with 40 grams in 1942, according to the War Production Board. This use is expected to decline because the number of aircraft dials radium-coated has been reduced to the most essential six per plane to avoid night blindness of pilots; other dials will be fluorescent and activated by ultraviolet (invisible) lamps illuminated only at certain intervals. Radium pigments made by mixing 1 part of radium with about 4,000 parts of phosphorescent zinc sulfide retain their luminosity some 6 to 8 years, after which the sulfide crystals are destroyed. Poisoning is still a problem in that phase of the industry.[41] In 1943 about 25 grams of radium were put into medical and industrial radiographic use, largely the latter. In the inspection of heavy castings and welds, the use of radium has increased almost equally with X-rays as a source of radiation;[42] greater utilization of both techniques will undoubtedly be made after the war than before.[43] Radium diffusion for measuring large quantities of water was tried experimentally.[44] The number of radioactive specimens tested annually by the National Bureau of Standards gives some index as to demand. Such specimens contained 35,193 milligrams of radium and 2,276 milligrams of mesothorium in 1943 compared with 16,408 and 2,139 milligrams, respectively, in 1942. A method of analyzing small quantities was described.[45] Polonium, a byproduct of radium, is a radioactive metal plated on spark plugs to ionize the air gap.[46]

Radioactivated elements.—Atom-smashing cyclotrons are bestowing the property of radioactivity upon a dozen common elements for use in medicine and industry. The use of radiophosphorus as a tracer in experimental steel melts, for example, demonstrated that phosphorus impurities of cast iron and steel concentrate around the blowholes on the surface. The presence and distribution of carbon, sulfur, manganese, and silicon in steel can likewise be determined.[47] In the medical field, artificially radioactivated elements are superior to radium and X-rays in their ability to migrate to cancerous tissue without harming healthy tissue. Cancer of the bone, for example, is treated with radiostrontium and radiocalcium, both of which (after being taken into the body) go immediately to the bones, particularly to new-forming tissue and cancerous growths in bones. Small tracer doses of these elements also give information about the action of vitamin D in rickets. Radiophosphorus is used in the treatment of blood diseases like leukemia, and radio-iodine in the treatment of tumors and enlargement of the thyroid gland. Radiosulfur has been used with vitamin B_1 to indicate how much of the vitamin the body retains and how long. Radiorubidium and radiopotassium are useful tools for studying the life processes of living plants.

Uses of uranium.—Most of the 1943 uranium supply was used by physics laboratories for research on uranium isotopes as a source of energy. The principal pre-war outlet for uranium was as a colorant in ceramics, but this use was largely prohibited by the War Production Board, January 26, 1943 (Order M-285). Pottery manufacturers have subsituted a combination of iron and antimony for uranium.[48] Several thousand pounds of uranium compounds were allowed to be consumed in 1943 in amber signal lenses and in glass of specific coefficient of expansion for glass-to-metal contacts in radio tubes.

Foreign production.—The Canadian Government placed sales of radium and uranium under permit control February 15, 1943,[49] reserved to the Crown all future discoveries of radioactive substances in the Northwest Territories and Yukon,[50] and took over the assets of the world's principal producer, Eldorado Mining & Refining, Ltd. (formerly Eldorado Gold Mines, Ltd.), January 28, 1944. The 3,905,046 shares were purchased at $1.35 a share; stock quotations had ranged between 21 cents and $1.64 a share in 1940–44 and 86 cents and $8.10 a share in 1933–34.[51] Exploration [52] and refining [53] of Canadian ores were described. Bear Exploration & Radium, Ltd., sold its Contact Lake silver-radium mine (9 miles southeast of the Eldorado mine) to International Uranium Mining Co., Ltd.[54]

[54] Northern Miner, B. E. A. R. to Offer Proposals: Vol. 29, No. 51, March 9, 1944, p. 14.

Work at the large radium-uranium deposit of Union Minière du Haut Katanga at Shinkolobwe, 10 miles southwest of Jadotville, Belgian Congo, was suspended in 1937 and apparently resumed in 1942, when the production was 1,021 metric tons of uranium ore containing 695.6 tons of U_3O_8. The company refinery at Oolen, Belgium, has been inaccessible to the United Nations since May 1940, but arrangements have been made to refine some Congo ore in Canada. The work of the Radium Institute of the Academy of Science of the U. S. S. R. "led to the discovery of new deposits of radioactive substances in the Soviet Union and laid the foundation of the extensive radium industry of the country"; the institute built the first cyclotron in Europe in 1937.[55] British-owned Companhia Portuguesa de Radium, Ltd., shipped 600 kilograms of radium salts [56] (estimated to contain 4.5 grams of radium) to United Kingdom in 1942. There was no Portuguese production of radium and uranium in 1943. Britain depends principally on Canadian supplies of radium, uranium, and mesothorium. The State-owned shale-oil plant at Kvarntorp, Province of Narke, Sweden, yields a residue containing uranium and other metals which may be extracted in future.[57] Exploration has revealed 25,000 tons of uranium ore (2 percent U) at Goten, 13 miles northeast of Sofia, Bulgaria.[58]

RHENIUM

Flue dust obtained from roasting domestic molybdenum ore has been found by A. D. Melaven and J. A. Bacon of the University of Tennessee to contain 1–1.5 percent rhenium in readily recoverable form.[59] The metal was first isolated in 1925 in Germany, and the few pounds produced in that country before World War II had constituted the total world output known hitherto. Rhenium is ductile, high-melting, and dense and has been used in catalysts, filaments, pen points, and electrical contacts.

SELENIUM AND TELLURIUM

Domestic production.—Selenium production increased 26 percent in 1943 compared with 1942, establishing a new record; producers' shipments climbed 65 percent but did not reach the 1941 level. Tellurium production in 1943 was only a fourth of that in 1942, and sales dropped 37 percent to pre-war levels. Stocks remained large. Producers of refined selenium and tellurium are the American Smelting & Refining Co., International Smelting & Refining Co., United States Metals Refining Co., and United States Smelting, Refining and Mining Co. Silver slimes containing selenium and tellurium are produced by Phelps Dodge Refining Corporation. All the selenium and most of the tellurium refined come from the tank slimes of electrolytic copper refineries; some tellurium is a byproduct of lead.

Salient statistics of elemental selenium and tellurium in the United States, 1939–43

Year	Selenium					Tellurium [1]		
	Production (pounds)	Producers' sales [2] (pounds)	Producers' stocks at end of year (pounds)	Imports [3]		Production (pounds)	Producers' sales [2] (pounds)	Producers' stocks at end of year (pounds)
				Pounds	Value			
1939	227,131	345,726	246,800	124,830	$193,168	25,234	63,431	39,100
1940	328,731	368,709	206,800	134,429	198,163	85,622	88,996	35,700
1941	620,493	681,650	146,000	197,873	288,161	224,639	239,983	20,400
1942	506,426	316,613	341,900	83,666	127,004	224,132	98,798	145,700
1943	635,581	521,779	455,677	81,720	142,032	56,174	62,260	139,403

[1] Includes tellurium content of small quantity of oxide.
[2] Bureau of Mines not at liberty to publish value. Quantities for 1942–43 represent producers' shipments.
[3] Includes selenium salts.

Foreign trade.—All selenium imports in 1942–43 came from Canada, except a few hundred pounds from the United Kingdom. Tellurium is not shown separately in import statistics. Producers reported exporting 7,218 pounds of selenium (including Se content of compounds) and 233 pounds of tellurium in 1943 compared with 5,550 pounds of selenium and 150 pounds of tellurium in 1942. Dealers may have exported additional quantities.

Prices.—The nominal price of selenium (black, powdered, 99.5 percent) and of tellurium continued to be $1.75 a pound throughout 1943, according to E&MJ Metal and Mineral Markets. Barium selenite and sodium selenite were quoted at $1.40–$1.65 a pound by Glass Industry.

Uses.—Selenium is used to decolorize clear glass, make rectifiers,[60] and improve the machinability of stainless steels, copper alloys, and "invar."[61] Cadmium sulfoselenide red pigments are used in signal lenses and, before the cadmium shortage, in many other products. Most of the tellurium supply and some selenium are added to rubber cable coverings to promote resistance to heat, oxidation, and abrasion and to increase resilience. Tellurium-lead work-hardens and is resistant to acids.

Foreign production.—Canada produced 380,200 pounds (preliminary figure) of selenium in 1943 compared with 495,369 pounds in 1942 and 406,930 pounds in 1941. The Dominion's tellurium output was 61,300 pounds (preliminary figure) in 1943 compared with 11,084 pounds in 1942 and 11,453 pounds in 1941. The principal producer is Canadian Copper Refiners, Ltd. (subsidiary of Noranda Mines, Ltd.), Montreal East, Quebec; and the other is Ontario Refining Co. (subsidiary of International Nickel Co. of Canada, Ltd.), Copper Cliff, Ontario. The former company expanded its selenium-recovery facilities in 1944. A similar expansion was completed by the Boliden Mining Co., Sweden, in 1943.

THALLIUM

Thallium output was increased somewhat in 1943 by the sole domestic producer, the American Smelting & Refining Co., which recovers the metal as a byproduct of cadmium operations at Denver, Colo., and converts most of it to sulfate—an odorless, tasteless poison used in rodent and ant control. Thallium sulfate requirements of the Fish and Wildlife Service and cooperative organizations were about 10,000 pounds in 1943 (compared with 7,500 in 1942 and 3,500 in 1941), and private companies wanted at least an additional 3,000 pounds, but in view of the interruption of imports from Europe, supply was only one-third of demand. Thallium metal is quoted at $10 a pound by E&MJ Metal and Mineral Markets. The sulfate (99 percent) has been listed at $12.50 a pound by Oil, Paint and Drug Reporter since September 1942, before which it was $5–$7 a pound.

[61] Steel, Low-Expansion Alloy Made Free-Machining: Vol. 112, No. 26, June 28, 1943, pp. 90, 92.

ZIRCONIUM

Domestic production.—Marketable zircon production in the United States totaled several hundred tons in 1940–43 compared with no output in 1929–39 and 3,646 short tons in 1927. The principal domestic producer at present is the Riz Mineral Co., which operates a concentrator at Melbourne, Brevard County, Fla.; the ore feed is black sand—formerly from stretches of beach near Melbourne but now from dunes about 3 miles inland from Vero Beach, Indian River County. St. Johns River Lumber & Development Co., St. Augustine, St. Johns County, Fla., shipped a small quantity of mixed ilmenite-rutile-zircon concentrates in 1943. Two companies produced crude zircon concentrates in 1943 for bringing up to marketable grade at a later date—Rutile Mining Co. of Fla. (subsidiary of Titanium Alloy Manufacturing Co.), as a byproduct of rutile and ilmenite from sand dunes between Jacksonville, Duval County, Fla., and the Atlantic coast; and Southwestern Engineering Co. (agent for Government-owned Metals Reserve Co.), as a byproduct of chromite from beach sands in Coos County, Oreg. The Oregon output was 2,143 short tons, averaging 27 percent ZrO_2. Beach deposits in Santa Rosa, Escambia, and Okaloosa Counties near Pensacola, Fla., are estimated to contain 750,000 tons of material averaging 1.2 percent kyanite, 1.0 percent ilmenite, 0.4 percent zircon, and 0.1 percent rutile.

Foreign trade.—Imports of zirconium concentrates are shown in the following table. There were no imports of zirconium ferroalloys in 1941–43. Exports in 1943 comprised 94 short tons ($7,805) of zirconium concentrates, 90 tons ($23,579) of alloys and metal, and 211 tons ($66,310) of compounds.

Zirconium concentrates imported for consumption in the United States, 1939–43, by countries, in short tons[1]

Year	Zircon from—				Baddeleyite from Brazil	Accessory titanium minerals[2]	Total zirconium concentrates[3]	
	Australia	Brazil	India	Total			Short tons	Value
1939	1,526	(4)	241	1,767	[4] 706	960	3,433	$49,919
1940	7,387	(4)	3,609	10,996	[4] 1,591	4,258	16,845	252,749
1941	14,689	(4)	963	15,652	[4] 5,002	7,020	27,674	604,744
1942	11,145	----------	196	11,341	15,283	7,282	33,906	816,364
1943	11,472	110	----------	11,582	8,821	8,009	28,412	697,704

[1] Totals and country break-down by the U. S. Department of Commerce. Mineral break-down by Bureau of Mines.
[2] Rutile and ilmenite content of mixed zirconium-titanium concentrates imported from Australia.
[3] Classified as "ore" by U. S. Department of Commerce.
[4] Zircon imports from Brazil, 1939–41, included with baddeleyite.

Consumption and uses.—Zircon shipments to consumers were 8,954 tons in 1943 compared with 5,766 tons in 1942. Zircon is used in ceramics, chiefly as an opacifier in porcelain enamels and pottery glazes but also as a constituent of refractories, electrical and chemical porcelains, grinding balls, and resistant glasses. Zirconia is advantageous in electrical heating units because it is both a conductor of heat and an insulator of electricity. Zircon refractories line many aluminum remelt furnaces. One of the largest uses of zircon is as a foundry sand. Zirconyl sulfate is a white tanning agent comparable with or superior to chrome.[62] Zirconium metal, the most explosive metal powder,[63] is used in radio tubes,[64] blasting caps, and flares.

Stocks.—Distributors' stocks of zircon (including zircon content of zirconium-titanium concentrates) were 8,197 short tons at the end of 1943 compared with 6,705 in 1942 and 6,549 in 1941. Government-owned Metals Reserve Co. stocks were 5,040 tons of zircon and 14,599 tons of baddeleyite at the end of 1943 compared with 4,500 tons and 4,156 tons, respectively, at the end of 1942. Large zircon stocks have resulted primarily from the strong demand for rutile, imported as mixed zircon-rutile-ilmenite concentrates from Australia.

Prices.—Zirconium ore, 55 percent ZrO_2, f. o. b. Atlantic seaboard, was quoted nominally at \$60–\$70 a short ton in January to March 1943, \$70–\$80 in early April, and \$65–\$75 from late April to the end of the year, according to E&MJ Metal and Mineral Markets. Glass Industry listed refined zircon at 6½ cents a pound in January to July 1942, 5¾ cents from August 1942 to January 1943, and 3½ cents after February. Zirconium ferrosilicon continued to be quoted at \$102.50–\$107.50 a long ton for 12- to 15-percent Zr content and 14–16 cents a pound for 35–40 percent Zr; and powdered zirconium metal at \$7 a pound.

SURVEY OF THE BITUMINOUS-COAL AND LIGNITE INDUSTRY IN 1943

The production of soft coal reached a new all-time high in 1943, with an estimated output of 589,000,000 net tons compared with the previous peak of 582,692,937 net tons in 1942. Although production was the greatest on record it still was not sufficient to meet the demand created by the expanding war economy. There were several interruptions to production due to labor difficulties. According to the Bureau of Labor Statistics there were 400 strikes in soft-coal mines in 1943, with 487,474 workers involved, 7,510,377 man-days lost, and an average of 15 days lost per man. It is estimated that the loss in production due to labor difficulties amounted to 35,000,000 net tons. Other causes for loss of production included difficulty in obtaining supplies and machinery and shortage of men. However, the loss of men was offset, in part, by increases in working time. By January 1943, with a few exceptions, the 6-day week was in effect throughout the industry. On November 3, 1943, a new wage contract was signed, extending the working time to 8 hours per day.

Production.—The outstanding feature related to the production of 589,000,000 net tons in 1943 was the elimination of seasonal declines, due largely to the Government program urging consumers to build up stocks during the summer. Throughout most of the year production remained near 12,000,000 net tons per week, except when output was reduced because of labor difficulties.

---

[1] Data for 1943 are preliminary; detailed statistics with final revisions will be released later. Data for 1942 are final. Information compiled in cooperation with the Solid Fuels Administration for War.

Consumption.—Although most of the major classes of consumers used more coal in 1943 than in 1942, there were certain exceptions; for instance, beehive ovens, coal-gas retorts, and cement mills burned less coal in 1943 than in 1942. Table 7 shows trends in consumption for the major classes of consumers.

Changes in stocks.—Owing to the shortage of coal, the reserve supply in the hands of industrial consumers and retail coal yards declined from a total of 85,889,000 net tons at the beginning of 1943 to 56,686,000 net tons at the close. The days' supply of stocks dropped from 51 to 30. Between the same periods stocks on the upper Lake docks declined 1,363,620 net tons, while unbilled coal in cars at the mines or classification yards fell 95,700 net tons.

Distribution.—Shipments of bituminous coal and lignite during 1943 showed only slight changes above or below the 1942 level in each of the primary channels of distribution. Table 12 shows trends in distribution of bituminous coal for 1937–43. Changes in the monthly volume of the more important movements are shown in figure 9.

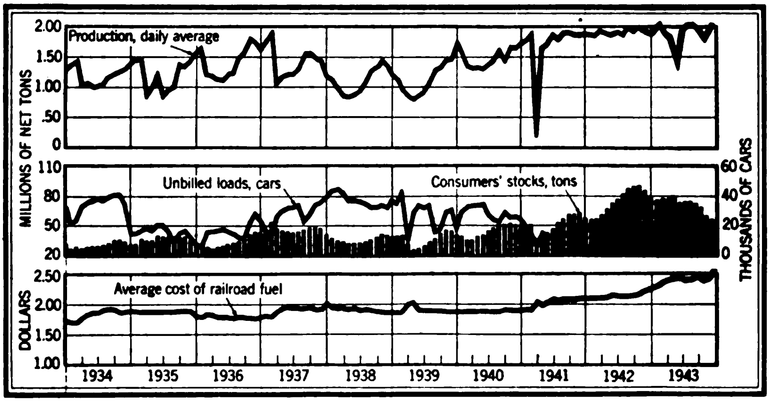

FIGURE 1.—Trends of production, stocks, and prices of bituminous coal and lignite in the United States 1934–43.

Mechanization.—The quantity of coal loaded mechanically at underground mines in the United States continued to advance during 1943. Preliminary estimates show that mechanical loading increased from 39.6 percent of the total output in 1942 to 42.4 percent in 1943, even though sales of underground loading equipment, in terms of capacity, were 32 percent less than in 1942.

Mechanical cleaning.—The total capacity of mechanical-cleaning equipment sold for use at bituminous-coal mines in 1943 was estimated at 3,500 net tons of cleaned coal per hour as compared with 6,400 net tons in 1942.

Trend of employment.—An estimate of the average number of men employed at bituminous-coal and lignite mines in 1943 indicates a sharp drop to 428,000 men from 461,991 in 1942.

Index to capacity.—The potential output upon a 308-day basis was 730,000,000 net tons in 1942. Under the 5-day week, full-time operation is limited to approximately 261 days. The average output per working day was 2,368,670 net tons during 1942, which (if applied to 261 days) gives an annual potential output of 618,000,000 tons compared with the actual total production of 582,692,937 net tons.

Trend of fuel efficiency.—For many years before 1942 there was a steady trend toward increased fuel efficiency. During 1942 and 1943 this trend was arrested or reversed, and some industries exhibited decreased fuel efficiency (see table 8).

Competition of oil and gas.—In 1943, as in 1942, competition among the various fuels was far outweighed by the urgent need for sufficient production of all fuels to satisfy the continued increase in demand.

Electric power utilities consumed 17 percent more bituminous coal, 18 percent more fuel oil, and 28 percent more gas in 1943 than in 1942.

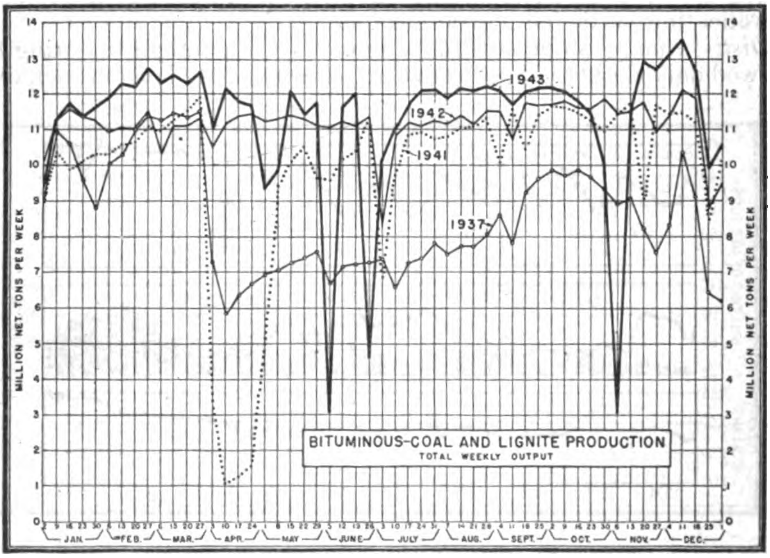

FIGURE 2.—Production of bituminous coal and lignite in the United States, by weeks, 1937 and 1941–43.

Class 1 railroads increased their consumption of coal by 13 percent in 1943 and their purchases of fuel oil by 16 percent over 1942.

Further curtailment of the manufacture of domestic fuel-burning equipment is reflected by statistics published by the Bureau of the Census. Factory sales of domestic stokers were reduced from 62,753 in 1942 to 4,460 in 1943; shipments of domestic oil burners, boiler-burner units, and furnace-burner units decreased from 82,388 in 1942 to 27,956 in 1943.

SOURCES OF DATA

Bituminous-coal and lignite production statistics for 1943 are preliminary estimates based upon (1) weekly or monthly reports of railroad carloadings of coal and beehive coke by all the important carriers, (2) shipments by river as reported by the United States Army Engineers, (3) direct reports from a number of mining companies, and (4) monthly production statements compiled by a number of local operators' associations and State mine departments. In the

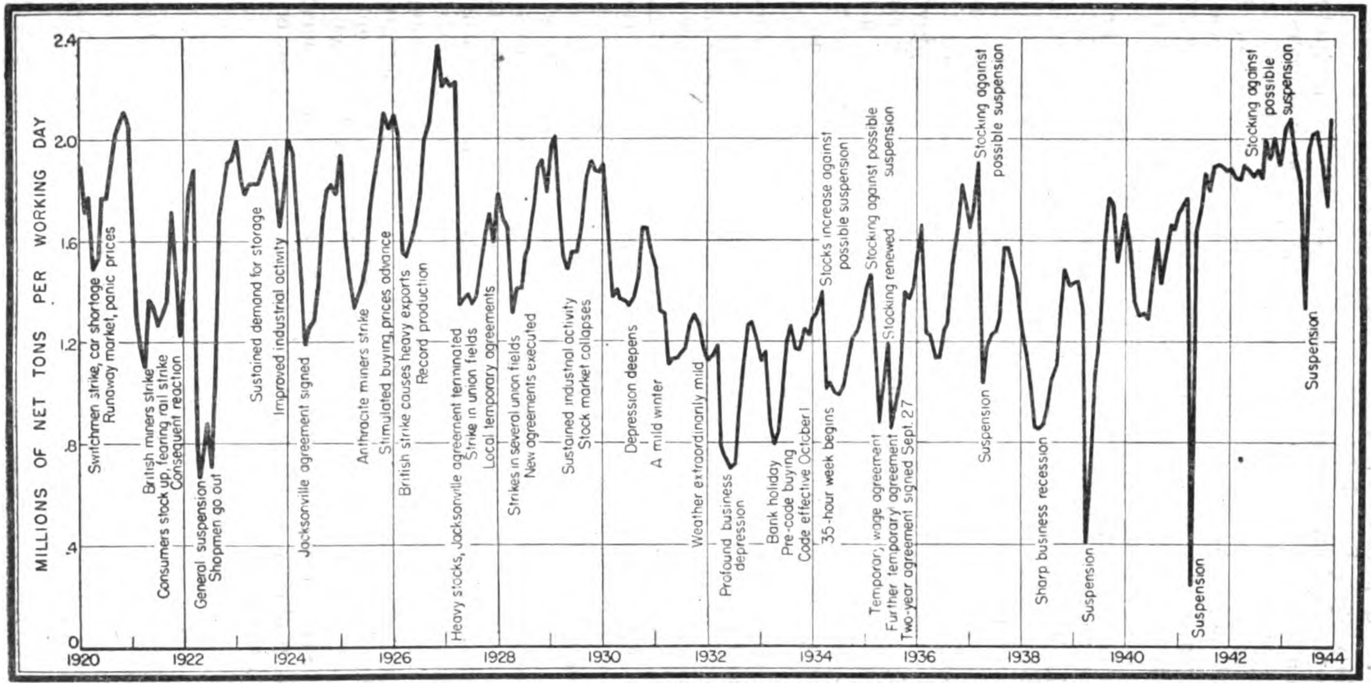

FIGURE 3.—Average production of bituminous coal and lignite in the United States per working day in each month, 1920–43.

estimates for 1943, allowance has been made for commercial truck shipments, local sales and colliery fuel, and small trucking or wagon mines producing over 1,000 tons a year.

Data for 1942 are final and are based upon detailed annual reports of production and mine operation furnished by the producers. As in previous years, all but a small percentage of the output was covered by the reports submitted. For the remaining output not directly reported, consisting chiefly of small mines, it has been possible to obtain reasonably accurate data from the records of the State mine departments, which have statutory authority to require such reports, or, in a few instances, from railroad carloadings.

Final figures of output and employment obtained from the annual canvass of production as shown in this report for 1942 differ slightly from those obtained from the annual canvass of accidents as published March 29, 1944, in Mineral Industry Surveys HSS 333. According to the production canvass, the output was 582,692,937 net tons and average number of men employed amounted to 461,991, while, according to the accident canvass of soft-coal mines, the production was 581,704,840 net tons and average men employed was 448,797. There are two major causes for this slight discrepancy in the two series of data. First, the coverage was not identical; that is, some mines were covered by the production canvass and not covered by the accident canvass, and vice versa. On an over-all basis, the production canvass included 6,972 mines, whereas the accident canvass included 6,940 mines. Since the question on production was asked in substantially the same form on both canvasses, the discrepancy in output figures is due largely to the difference in coverage, while the discrepancy in employment is due partly to other causes. Second, producers reported for identical mines different figures of output and employment on the production canvass from those reported on the accident canvass. Although this cause is only slightly responsible for the discrepancy in the output figures, it is very significant in explaining the discrepancy in the employment series. The principal reason for the producers reporting different figures of employment for the same mine was that the question on employment on the production canvass was asked in a slightly different form to the way it was in the accident canvass. The wording of the question on employment in the production canvass tends to count the employee who works only part of the year and at the same time not give complete consideration to absenteeism. Since the employment series from the accident canvass tends to discount the employee who leaves the industry during the year as well as discount absenteeism, this figure is probably a better measure of changes of manpower in the soft-coal industry.

SALIENT STATISTICS

TABLE 1.—*Salient statistics of the bituminous-coal and lignite industry in the United States, 1942–43*

[All tonnage figures represent net tons]

	1942	1943 (preliminary)	Change in 1943
			Percent
Production	582, 692, 937	589, 000, 000	+1.1
Consumption in the United States [1]	540, 629, 000	594, 552, 000	+10.0
Stocks at end of year:			
Industrial consumers and retail yards	85, 889, 000	56, 686, 000	−34.0
Stocks on upper Lake docks	6, 993, 030	5, 629, 410	−19.5
Unbilled loads, at mines or in classification yards [2]	139, 700	44, 000	−68.5
Price indicators (average per net ton):			*Cents*
Average cost of railroad fuel purchased, f. o. b. mines [3]	$2.13	$2.42	+29
Average cost of coking coal at merchant byproduct ovens [4]	$4.98	$5.21	+23
Average retail price—35 cities [5]	$9.53	$9.94	+41
Average railroad freight charge per net ton [6]	$2.31	$2.30	−1
Underground loading machinery sold: [7]			*Percent*
Mobile loading machines (number)	352	234	−33.5
Scrapers (number)	15	13	−13.3
Pit-car loaders (units)	2	1	−50.0
Conveyors, including those with duckbills (units)	1, 167	798	−31.6
Average number of men employed at mines operating [8]	461, 991	428, 000	−7.4
Fuel-efficiency indicators:			
Pounds of coal per kilowatt-hour at electric power plants [9]	1.31	1.31	....
Pounds per 1,000 gross ton-miles—railroads [10]	111	114	+2.7

[1] Represents certain classes of consumers only. See table 7 for consumers included.

[2] Association of American Railroads.

[3] Interstate Commerce Commission (class I steam railways, including class I switching and terminal companies). Excludes freight charges.

[4] As reported by coke operators.

[5] Bureau of Labor Statistics.

[6] Average receipts per net ton of revenue bituminous coal and lignite originated, as reported by the Interstate Commerce Commission.

[8] The figure for 1942 is based upon reports of mine operators producing over 1,000 tons. The figure for 1943 is estimated from various sources.

[9] Federal Power Commission.

[10] Interstate Commerce Commission; includes coal equivalent of fuel oil consumed.

PRODUCTION BY WEEKS AND MONTHS

The following tables summarize the preliminary statistics of weekly and monthly production of bituminous coal and lignite in 1943. The figures are estimates based upon daily and weekly statements of cars of coal and beehive coke loaded by the principal railroads and of shipments over the more important originating rivers. Allowance has been made for commercial truck shipments, local sales, and colliery fuel. The estimates given are based upon the latest information available and differ in some instances from the current figures previously published in the Weekly Coal Reports.

For the method used in counting holidays, see the chapter on Coal in Mineral Resources of the United States, 1930, page 631.

	589,000,000	309.4	1,904,000

[1] Figures represent output and number of working days in that part of the week included in the calendar year shown. Total production for the week of Jan. 1, 1944, was 10,500,000 net tons; for the week of Jan. 2, 1943, was 9,479,000 net tons.

[2] Average daily production for the entire week and not for the working days in the calendar year shown.

TABLE 3.—*Estimated monthly production of coal in the United States, by States, in thousands of net tons, in 1943*

[Bituminous and lignite figures are preliminary estimates based on railroad carloadings and river shipments of coal and beehive coke, supplemented by direct reports from a number of mining companies, local coal operators' associations, and detailed monthly production statistics compiled by the State Mine Departments of Colorado, Illinois, Pennsylvania, Washington, and West Virginia. In making the estimates, allowance is made for commercial truck shipments, local sales, and colliery fuel, and for small trucking mines producing over 1,000 tons a year. Where a mine is on the border between two States, the production is accredited to the State from which the coal is extracted, rather than the State in which the tipple is located. The estimates here given differ in a few cases from the current figures previously published in the Weekly Coal Reports]

State	January	February	March	April	May	June	July	August	September	October	November	December	Total

[1] Subject to revision. Includes Sullivan County, washery and dredge coal, local sales, colliery fuel, and coal shipped by truck from authorized operations.

TABLE 4.—*Estimated monthly production of bituminous coal and lignite in the United States, by districts, in thousands of net tons, in 1943*

[Districts as defined in the Bituminous Coal Act of 1937 and modifications thereto. Exclusive of mines producing less than 1,000 tons a year]

[Figures are based principally upon the records of railroad carloadings and river shipments of coal and beehive coke, supplemented by direct reports from certain local sources, which are used in estimating State production. Allowance is made for commercial truck shipments, local sales, and colliery fuel, and for trucking mines producing over 1,000 tons a year. These records are sufficient to permit estimating the total production of coal for the United States with a high degree of accuracy. To apportion the totals among the districts involves a larger measure of estimate and hence the district tonnages are subject to a larger measure of correction when final complete reports are received from all operators at the end of the year]

1939	2, 565	43, 979	79, 072	2, 298	61, 216	9, 808	1, 614	5, 274	98, 900	71, 570	376, 296
1940	2, 443	50, 973	85, 130	4, 803	76, 583	10, 040	1, 746	5, 633	106, 280	87, 700	431, 331
1941	2, 489	61, 861	97, 384	10, 529	82, 609	10, 902	1, 659	6, 832	120, 720	97, 460	492, 445
1942	2, 708	65, 636	115, 410	12, 876	87, 974	10, 434	1, 721	7, 570	131, 550	104, 750	540, 629
1943 [5]	2, 739	76, 401	130, 283	12, 441	90, 019	11, 238	1, 605	5, 851	141, 211	122, 764	594, 552

[1] These data have been assembled to show changes in consumption of bituminous coal and lignite by such classes of consumers as report currently. The total, including retail deliveries, does not represent grand total consumption in the United States. Bunker-fuel statistics are not available for publication at present. The "total of classes shown" for each year in the above table cannot be reconciled with the calculated consumption obtained by the formula: "Production plus imports minus exports plus or minus net changes in consumers' stocks" due to the omission of bunker fuel; to revisions in data covering production, exports, and imports; and to unavoidable irregularities that occur in reports from respondents who are unable to require that definitions applied and closing dates observed by their accountants are identical with those generally used in the surveys of bituminous-coal and lignite consumption.
[2] Geological Survey and Federal Power Commission. Represents bituminous coal and lignite consumed by public utility power plants in power generation, including a small quantity of coke amounting to approximately 100,000 tons annually.
[3] Association of American Railroads. Represents the consumption of bituminous coal and lignite by class I railways, for all uses, including locomotive, powerhouse, shop, and station fuel. The Interstate Commerce Commission reports that in 1942 the consumption for all uses by class I line-haul railways plus the purchases for class II and class III railways, plus purchases by all switching and terminal companies combined, was 122,208,266 net tons of bituminous coal and lignite. Similar data from the Interstate Commerce Commission are not yet available for 1943.
[4] Estimates based upon reports collected by the Solid Fuels Administration for War from a selected list of representative manufacturing plants.
[5] Subject to revision.

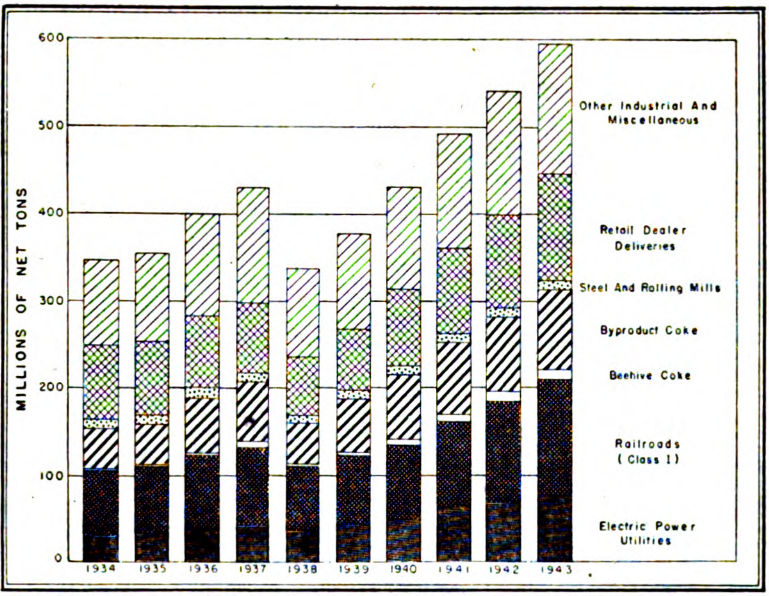

FIGURE 5.—Consumption of bituminous coal and lignite, by consumer class, with retail deliveries in the United States, 1934–43.

FUEL EFFICIENCY

TABLE 8.—*Indicators of effect of fuel economy on consumption of coal in the United States per unit of performance since the World War of 1914–18*

	Pounds	Reduction from base period (percent)
Steam railroads:		
Pounds per 1,000 gross ton-miles freight service:		
Average:		
1919–20	170	
1942	111	34.7
1943	114	32.9
Pounds per passenger-train car-mile:		
Average:		
1919–20	18.5	
1942	15.1	18.4
1943	15.0	18.9
Electric public-utility power plants:		
Pounds per kilowatt-hour:		
1919	3.2	
1942	1.3	59.4
1943	1.3	59.4
Iron and steel-pounds coking coal per net ton of pig: [1]		
1918	3,194	
1942	2,604	18.5
1943	2,620	18.0
Coke manufacture: Savings of heat values through recovery of gas, tar, light oils, and breeze by extension of byproduct in place of beehive coking, 1913–43, expressed as percent of coal used for all coke in 1943 [2]		18.5

---

[1] Includes only savings through higher yields of merchantable coke per ton of coal charge and lower consumption of coke per ton of iron. Excludes economies through recovery of byproducts, which are covered in next item.

[2] These byproducts are used in part for boiler fuel, in part for metallurgical purposes, in part for domestic heating and coking, and to a small extent for automotive fuel.

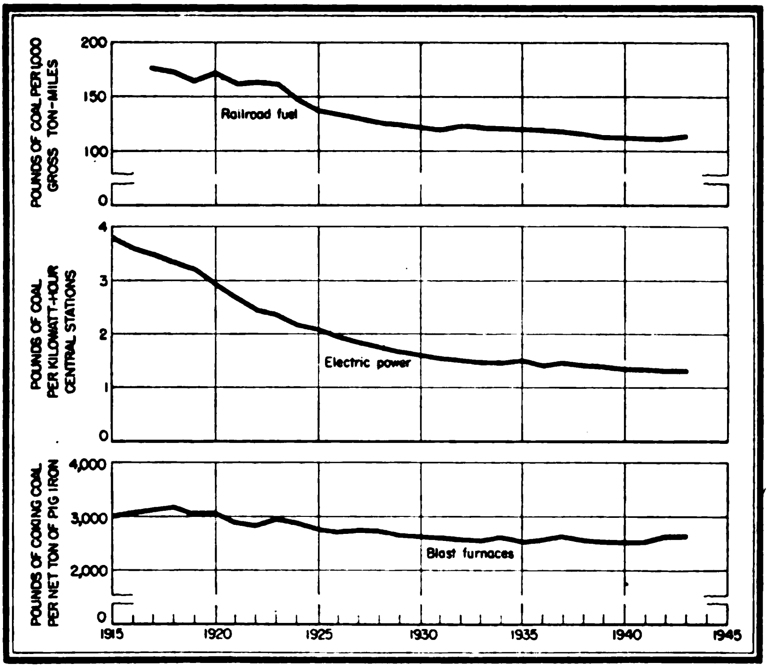

FIGURE 6.—Trends of fuel efficiency in the United States, 1915–43.

RELATIVE RATE OF GROWTH OF COAL, OIL, AND WATER POWER, 1889–1943

According to preliminary data, the total supply of available energy in the form of coal, oil, natural gas, and water power in 1943 was 33,712 trillion B. t. u.—a 5.4-percent increase over 1942 (see fig. 7). The figures are expressed in British thermal units because some common denominator is necessary for such unlike quantities as tons of coal, barrels of oil, and cubic feet of gas. Table 9 summarizes the equivalent of each of the fuels in trillions of British thermal units. Water power is represented by the equivalent fuel required to perform the same work. The table covers the years since 1933. Details for 1889 to 1932 are given in Minerals Yearbook, 1937, page 807.

In converting water power to its fuel equivalent, two alternative assumptions have been made. The first, as in previous issues of these tables, assumes a *constant* fuel equivalent of 4.02 pounds of coal for each kilowatt-hour of water power produced throughout the entire period from 1889 to 1943. This factor was selected because it represents, in round numbers, the average efficiency of all central stations generating steam-electric power in 1913, the midpoint of the period under review. The usefulness of the *constant* factor lies in showing the rate at which water power is being developed. It permits direct comparison between the relative increase (in kilowatt-hours of water power) and the corresponding increase or decrease (in tons of coal, barrels of oil, or cubic feet of gas produced). On the other hand, the *constant* factor makes no allowance for the fact that coal and other fuels produced today are used more efficiently than formerly.

To throw light on the influence of improving fuel efficiency, a second computation of the energy equivalent of water power has therefore been made. This assumes a *prevailing* fuel equivalent, diminishing year by year, which represents the average performance of all fuel-burning central electric stations for the year in question. This average has declined from about 7.05 pounds of coal per kilowatt-hour in 1899 to 1.31 pounds in 1943. (The *prevailing* factor is thus much above the *constant* factor in 1899 and much below it in 1943.) The *prevailing* fuel equivalent indicates more nearly the quantity of fuel that would have been needed in any one year to generate the same power in a steam-electric station. It should be noted, however, that the ultimate uses to which the water power generated is put, often displace fuel burned much less efficiently than in central stations and that in any instance no other important branch of fuel consumption has made advances in fuel efficiency approaching that of the central stations.

As these tables attempt to determine the total energy from all fuels and from water power, the ideal factor for converting water power into fuel equivalent would be the average efficiency of all forms of fuel consumption in each year. No basis for determining such an all-embracing average exists at present, but enough is known to make certain that it would show much less reduction from 1899 to 1943 than did the central stations. For the present, a just comparison of the changing contributions of water power and of fuel to the national energy supply would lie somewhere between the results shown by the *constant* equivalent and the *prevailing* central-station equivalent in these tables.

As in earlier issues of these tables, the figures for oil and natural gas represent the entire production of crude petroleum and of gas. Most of this production does not come into direct competition with coal. Much of the supply of both oil and gas is used in regions of the country, such as California and portions of the Southwest, where coal is available only at unusually high cost because of heavy transport charges. Nearly half of the natural gas is used in the field for drilling or operating oil and gas wells and pipe lines or for the manufacture of carbon black. More than half the oil is used in the form of gasoline, kerosene, and lubricants, for which purposes coal cannot well compete, except at very much higher levels of oil prices. Even these refined products, however, involve a certain measure of indirect competition with coal, for the energy market of the country is becoming more fluid and competitive, and a demand that cannot be met by one source of supply tends to fall back on the others.

The subject of interfuel competition is exceedingly complex, and an elaborate analysis and the accumulation of data not now available would be required to determine even approximately how much of any one fuel actually has been displaced either by other fuels or by water power. The present tables do not permit determination of such displacement; their purpose is rather to measure the long-time trends in the total demand for energy.

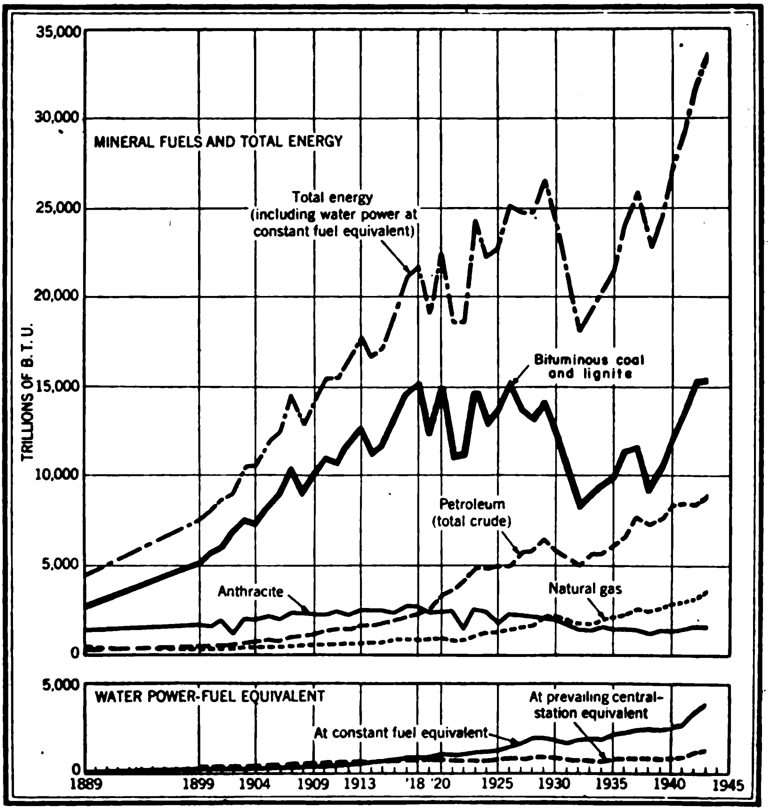

FIGURE 7.—Annual supply of energy from mineral fuels and water power in the United States, 1889–1943.

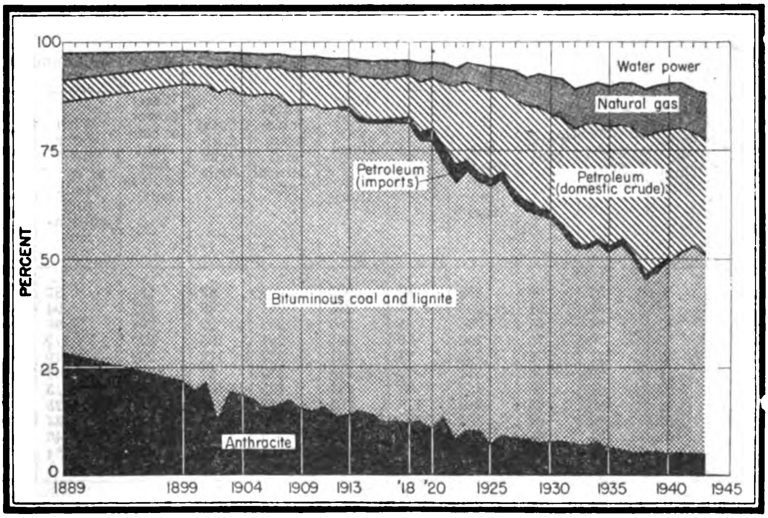

FIGURE 8.—Percentage of total B. t. u. equivalent contributed by the several sources of energy in the United States, counting water power at constant fuel equivalent, 1889–1943. If water power is counted at the prevailing fuel equivalent of central stations in each year, its proportion is 3.2 percent in 1899 and 4.2 percent in 1943, and the proportions of the other sources of energy are affected accordingly.

TABLE 9.—*Annual supply of energy from mineral fuels and water power in the United States, 1933–43,*[1] *in trillions of B. t. u.*[2]

Year	Pennsylvania anthracite	Bituminous coal and lignite	Total coal	Petroleum (total crude, including that refined)		Natural gas (total production)	Total petroleum and natural gas	Total mineral fuels	Water power (fuel equivalent)		Grand total energy	
				Domestic production	Imports				At constant fuel equivalent[3]	At prevailing central station equivalent[4]	Water power at constant fuel equivalent	Water power at prevailing central station equivalent

[1] Comparable data for earlier years in Minerals Yearbook, 1937, p. 807.

[2] The unit heat values employed are: Anthracite, 13,600 B. t. u. per pound; bituminous coal and lignite, 13,100 B. t. u. per pound; petroleum, 6,000,000 B. t. u. per barrel; natural gas, 1,075 B. t. u. per cubic foot. Water power includes installations owned by manufacturing plants and mines, as well as Government and privately owned public utilities. The fuel equivalent of water power is calculated from the kilowatt-hours of power produced wherever available, as is true of all public-utility plants since 1919. Otherwise, the fuel equivalent is calculated from the reported horsepower of installed water wheels, assuming a capacity factor of 20 percent for manufacturers and mines and of 40 percent for public utilities.

[3] Assuming 4.02 pounds per kilowatt-hour, which is the average of central electric station practice in 1913, the base period used.

[4] Assuming the average central-station practice for each of the years for which data are available, which declined from about 7.05 pounds per kilowatt-hour in 1899 to 1.31 pounds in 1943.

[5] Subject to revision.

[6] Excludes imports of crude petroleum. Figures not available for publication.

TABLE 10.—*Index numbers for relative rate of growth of coal, oil, and water power in the United States, 1933–43*[1]

[The figures are expressed as a percentage of the 1913 rate]

Year	Pennsylvania anthracite	Bituminous coal and lignite	Total coal	Petroleum (total crude)		Natural gas (total production)	Total petroleum and natural gas	Total mineral fuels	Water power (at constant fuel equivalent)	Grand total	
				Domestic production	Imports					With water power at constant fuel equivalent	With water power at prevailing central station equivalent

POST-WAR OUTLOOK

The post-war outlook for soft coal revolves around the general level of industrial activity and the extent of competition offered by other fuels. The consumption of soft coal follows very closely the trend of industry, since only a small fraction of the total is used for domestic space-heating. The accumulated demand for many products, particularly for automobiles, machinery, building materials, and household appliances, will doubtless stimulate industry for several years after the close of the war. Barring heavy inroads by competitive fuels, coal should participate in this anticipated activity.

Soft coal is in a better competitive position today than for many years. The shortage of fuel oil and anthracite has enabled soft coal to regain some of its lost markets. The shortage of pipe has retarded the expansion of natural-gas lines. Many consumers who have installed coal-burning equipment during the war will be hesitant to convert to oil or gas, since the life expectancy of the reserves of these fuels is somewhat doubtful. The present program for the development of liquid fuels from coal even indicates that in future coal may be replacing oil.

FINAL BITUMINOUS-COAL AND LIGNITE STATISTICS FOR 1942

Tables 14 to 61 give the final detailed statistics of bituminous-coal and lignite mine operations in 1942. The subjects covered include

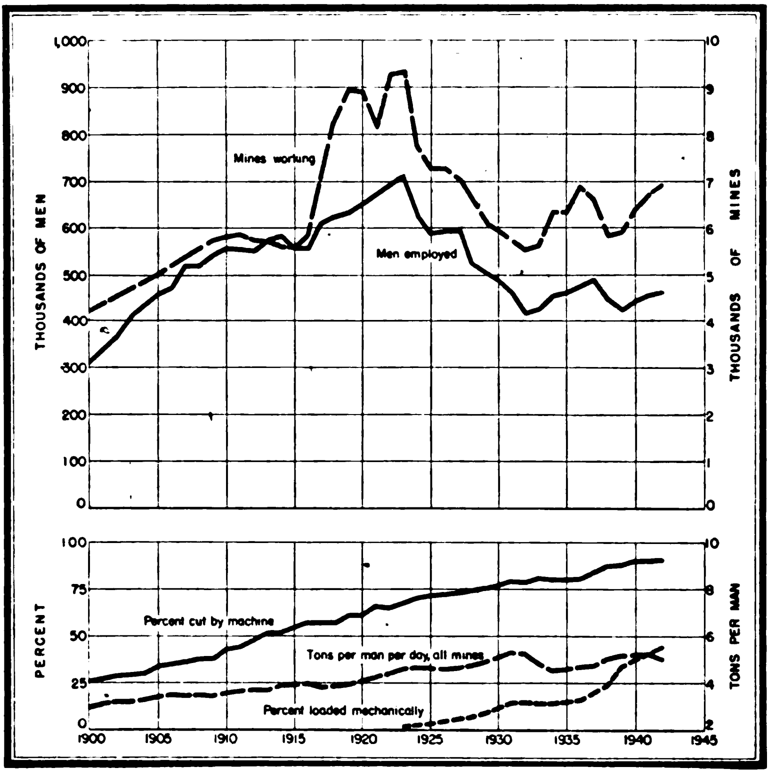

FIGURE 10.—Trends of employment, mechanization, and output per man at bituminous-coal and lignite mines in the United States, 1900–43.

production, number and size of mines, employment, value, mechanization, and world production.

In accordance with the practice followed by the Bureau of Mines in previous years, the statistics in this report relate to mines having an output of 1,000 tons a year or more and do not attempt to include many small mines producing less than 1,000 tons a year that sell their output by wagon or truck.

These statistics include, for convenience and historical comparison, the small output of anthracite and semianthracite produced outside Pennsylvania and the production of lignite.

SALIENT TRENDS

TABLE 14.—*Salient trends in bituminous-coal and lignite-mining industry in the United States, 1935–42*

	1935	1936	1937	1938	1939	1940	1941	1942
Production:								
Loaded at mine for shipment by rail……net tons..	319,741,376	370,762,901	[1] 399,237,575	295,336,027	331,189,620	380,387,674	425,184,319	482,814,042
Loaded at mine for shipment by water……do....	18,327,282	24,867,683	([1])	16,902,969	22,229,364	29,493,058	30,240,489	34,018,025
Shipped by truck or wagon……do....	21,960,252	27,929,298	[2] 37,762,612	25,592,058	29,533,824	35,540,476	40,055,638	45,154,432
Taken by locomotive tenders at tipple……do....	([3])	([3])	([2])	606,857	826,556	939,058	1,099,582	920,213
Shipped by conveyor or tram to point of consumption..do....	([3])	([3])	([2])	4,221,671	4,317,465	5,887,994	6,067,697	7,121,116
Used by mine employees……do....	[3] 7,773,619	[3] 9,571,997	([2])	2,032,289	1,901,408	2,035,201	1,872,026	2,180,077
Used at mines for power and heat……do....	3,102,691	3,227,447	3,052,095	2,493,017	2,565,276	2,442,989	2,488,950	2,708,312
Made into beehive coke at mines……do....	1,467,902	2,728,577	4,884,054	1,359,876	2,089,475	4,045,050	7,140,544	7,776,720
Total production……do....	372,373,122	439,087,903	[4] 445,531,449	348,544,764	[5] 394,855,325	460,771,500	514,149,245	582,692,937
Number of active mines of commercial size:								
Class 1 (200,000 tons or more)……number..	561	660	661	526	577	636	730	811
Class 2 (100,000 to 200,000 tons)……do....	479	452	469	402	404	432	437	484
Class 3 (50,000 to 100,000 tons)……do....	503	460	448	415	387	371	402	445
Class 4 (10,000 to 50,000 tons)……do....	1,056	1,085	1,117	1,042	1,065	1,157	1,305	1,492
Class 5 (1,000 to 10,000 tons)……do....	3,716	4,218	3,853	3,392	3,387	3,728	3,948	3,740
Total number over 1,000 tons……do....	6,315	6,875	6,548	5,777	5,820	6,324	6,822	6,972
Average number of men employed at mines active:								
Underground……men..	389,942	399,367	([6])	370,004	353,476	365,013	376,765	374,654
Surface:								
In strip pits……do....	8,533	8,043	([6])	7,877	8,791	8,983	10,861	12,893
All others……do....	63,928	69,794	([6])	63,452	59,521	65,079	69,355	74,444
Total……do....	462,403	477,204	491,864	441,333	421,788	439,075	456,981	461,991
Average number of days mines operated……days..	179	199	193	162	178	202	216	246
Capacity of active mines with existing labor force:								
Per year of 308 days……net tons..	640,000,000	680,000,000	710,000,000	663,000,000	683,000,000	703,000,000	733,000,000	730,000,000
Per year of 280 days……do....	582,000,000	618,000,000	646,000,000	602,000,000	621,000,000	639,000,000	666,000,000	663,000,000
Per year of 261 days……do....	543,000,000	576,000,000	601,000,000	562,000,000	579,000,000	595,000,000	621,000,000	618,000,000
Output per man per day……do....	4.50	4.62	4.69	4.89	5.25	5.19	5.20	5.12
Output per man per year……do....	805	920	906	790	936	1,049	1,125	1,261
Underground output cut by machine……do....	293,664,208	348,332,330	([6])	278,315,365	313,969,394	369,227,277	408,510,296	462,344,719
Percent of underground output cut by machine……percent..	84.2	84.8	([6])	87.5	87.9	88.4	89.0	89.7
Underground output mechanically loaded……net tons..	47,177,224	66,976,872	83,500,000	85,092,836	110,711,970	147,870,252	186,667,250	232,902,920
Percent of underground output mechanically loaded..percent..	13.5	16.3	20.2	26.7	31.0	35.4	40.7	45.2

See footnotes at end of table.

TABLE 14.—*Salient trends in bituminous-coal and lignite-mining industry in the United States, 1935–42*—Continued

	1935	1936	1937	1938	1939	1940	1941	1942
Quantity mined by stripping.....net tons..	23,647,292	28,125,857	31,750,853	30,406,855	37,722,583	43,167,336	55,071,609	67,202,663
Percent mined by stripping.....percent..	6.4	6.4	7.1	8.7	9.6	9.4	10.7	11.5
Quantity cleaned by wet or pneumatic processes [7].....net tons..	45,361,021	61,094,976	65,000,000	63,454,588	79,429,426	102,269,753	117,539,522	142,187,346
Percent cleaned by wet or pneumatic processes [7].....percent..	12.2	13.9	14.6	18.2	20.1	22.2	22.9	24.4

[1] In 1937, coal loaded at mine for shipment by water is included with "loaded at mine for shipment by rail."

[2] Coal "taken by locomotive tenders at tipple," "shipped by conveyor or tram to point of consumption," and "used by mine employees" included with "shipped by truck or wagon."

[3] In 1935 and 1936 data were not collected in such form as to permit a separation of coal "taken by locomotive tenders at tipple," "shipped by conveyor or tram to point of consumption," and "used by mine employees." They are all included here under "used by mine employees."

[4] The total production differs from the sum of the items shown by the amount of the changes in inventory and the tonnage not accounted for in the distribution analysis. This tonnage amounted to 595,113 net tons.

[5] Includes 202,337 tons of coal reported as net changes in stocks at mines Jan. 1, 1939, to Jan. 1, 1940.

[6] Data not available.

[7] Includes central washeries operated by consumers.

TABLE 15.—*Growth of bituminous-coal- and lignite-mining industry in the United States, 1890–1942*

Year	Production	Value [1]	Value per ton [1]	Men employed	Number of mines	Calculated capacity (millions of net tons)		
						At 308 days	At 280 days	At 261 days
1890	111, 302, 322	$110, 420, 801	$0. 99	192, 204	(2)	152	137	129
1891	117, 901, 238	117, 188, 400	. 99	205, 803	(2)	163	148	138

---

[1] Percentages for 1890 to 1913, inclusive, are of total production, as a separation of strip-mine and underground production is not available for these years.

[2] For the years 1906 to 1926, inclusive, these percentages are exclusive of coal cleaned at central washeries operated by consumers; after 1926, when data became available on the tonnage cleaned by consumer-operated plants, the percentages include the total tons cleaned at the mines and at consumer-operated washeries.

[3] Data not available.

[4] One-half day or less.

Table 16.—*Coal produced in the United States, by States, 1932–42, with production of maximum year and cumulative production from the earliest record to the end of 1942, in thousands of net tons*

State	Maximum production		Production by years											Total production from earliest record to end of 1942

SUMMARY BY STATES AND DISTRICTS

TABLE 17.—*Production, value, employment, days active, man-days, and output per man per day at bituminous-coal and lignite mines in the United States, by States, in 1942*

[Exclusive of mines producing less than 1,000 tons]

State	Disposition of coal produced (net tons)								Average value per ton [3]	Average number of employees				Average number of days mines were active	Number of man-days worked	Average tons per man per day
	Loaded at mine directly into railroad cars or river barges	Hauled by truck to railroad siding for shipment by rail and to waterway for shipment by water [1]	Shipped by truck or wagon (excluding coal used by mine employees)	Taken by locomotive tenders at tipple	Shipped by conveyor or tram to point of consumption	Used by mine employees	Used at mines for power and heat and made into beehive coke at mines [2]	Total quantity		Underground	Surface		Total			
											In strip pits	All others

---

[1] Includes coal hauled by truck to waterway for shipment by water in the following States in 1942: Alabama, 5,953 tons; Illinois, 137,461 tons; Kentucky, 617 tons; Ohio, 2,784 tons; Pennsylvania, 147,472 tons; Tennessee, 109,823 tons; and West Virginia, 317,340 tons; a grand total of 721,450 tons.

[2] Includes coal made into beehive coke at mines in the following States in 1942: Alabama, 26,756 tons; Colorado, 136,905 tons; Kentucky, 1,897 tons; Pennsylvania, 6,488,448 tons; Tennessee, 4,277 tons; Utah, 43,674 tons; Virginia, 563,356 tons; and West Virginia, 511,407 tons; grand total, 7,776,720 tons.

[3] Value received or charged for coal f. o. b. the mine, including the selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by the producer at average prices that might have been received if such coal had been sold commercially.)

[4] South Dakota includes Montana lignite.

[5] Since it is necessary to conceal certain items in the lignite break-down of disposition of coal, the figures are shown here in the column where the majority of the concealed tonnage appears.

TABLE 18.—*Number of mines, production, value, employment, days active, man-days, and output per man per day at bituminous-coal and lignite mines in the United States, by districts, in 1942*

[Districts as defined in the Bituminous Coal Act of 1937 and modifications thereto; exclusive of mines producing less than 1,000 tons]

Minimum price area and producing district	Number of active mines	Disposition of coal produced (net tons)								Average value per ton [3]	Average number of employees				Average number of days mines were active	Number of man-days worked	Average tons per man per day
		Loaded at mine directly into railroad cars or river barges	Hauled by truck to railroad siding for shipment by rail and to waterway for shipment by water [1]	Shipped by truck or wagon (excluding coal used by mine employees)	Taken by locomotive tenders at tipple	Shipped by conveyor or tram to point of consumption	Used by mine employees	Used at mines for power and heat and made into beehive coke at mines [2]	Total quantity		Underground	Surface		Total			
												In strip pits	All others

---

[1] Includes coal hauled by truck to waterway for shipment by water in the following districts in 1942: District 2, 147,472 tons; district 3, 165,514 tons; district 4, 2,784 tons; district 6, 30,285 tons; district 8, 121,541 tons; district 9, 617 tons; district 10, 137,461 tons; district 13, 115,776 tons; a grand total of 721,450 tons.

[2] Includes coal made into beehive coke at mines in the following districts in 1942: District 1, 471,580 tons; district 2, 6,016,868 tons; district 3, 166,001 tons; district 7, 345,406 tons; district 8, 565,253 tons; district 13, 31,033 tons; district 17, 136,905 tons; district 20, 43,674 tons; a grand total of 7,776,720 tons.

[3] Value received or charged for coal f. o. b. the mine, including the selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by the producer at average prices that might have been received if such coal had been sold commercially.)

[4] Includes Maryland and Grant, Mineral, and Tucker Counties, W. Va.

[5] Includes Colfax County, N. Mex.

[6] Includes Arizona and California, but excludes Colfax County, N. Mex. No production was reported for California.

[7] Includes Idaho. No production was reported for Idaho.

[8] North and South Dakota includes Montana lignite.

[9] Since it is necessary to conceal certain items in the lignite break-down of disposition of coal, the figures are shown here in the column where the majority of the concealed tonnage appears.

[10] Includes Oregon.

[11] For purposes of historical comparison and statistical convenience, the figures include the output of lignite and of anthracite and semianthracite outside of Pennsylvania.

PRODUCTION BY WEEKS AND MONTHS

---

[1] Figures represent output and number of working days in that part of the week included in the calendar year shown. Total production for the week of Jan. 3, 1942, was 10,121,000 net tons and for Jan. 2, 1943, 9,479,000 net tons.

[2] Average daily production for the entire week and not for the working days in the calendar year shown.

TABLE 20.—*Final coal production in the United States, by States, with estimates by months, in thousands of net tons, in 1942*

[The totals for the year are based on final complete returns from all operators known to have produced more than 1,000 tons a year. The apportionment of the known yearly total among the 12 months is based upon the best information available; in some States upon direct tonnage reports by operators to the State mine departments; in most cases upon current records of railway carloadings and waterway shipments]

[1] Includes Arizona and Oregon.

[2] Includes Sullivan County, washery and dredge coal, local sales, colliery fuel, and coal shipped by truck from authorized operations; also includes some "bootleg" coal purchased by legitimate operators and prepared at their breakers.

TABLE 21.—*Final bituminous-coal and lignite production in the United States by districts, with estimates by months, in thousands of net tons, in 1942*

[Districts as defined in the Bituminous Coal Act of 1937, and modifications thereto. Exclusive of mines producing less than 1,000 tons a year]

[The totals for the year are based on final complete returns from all operators known to have produced more than 1,000 tons a year. The apportionment of the known yearly total among the 12 months is based on the latest information available; in some States upon direct tonnage reports from operators to the State mine departments; in most cases upon current records of railroad carloadings and waterway shipments]

---

[1] Includes Maryland and Grant, Mineral, and Tucker Counties, W. Va.

[2] Data for lignite by classes in Montana, North Dakota, South Dakota, and Texas are not available for the separate States, but are shown at end of table in combined form as "Total lignite."

[3] Includes Colfax County, N. Mex.

[4] Includes Arizona and California, but excludes Colfax County, N. Mex. No production was reported for California.

[5] Includes Idaho. No production was reported for Idaho.

[6] Includes Oregon.

[7] For purposes of historical comparison and statistical convenience, the figures include the output of lignite and of anthracite and semianthracite outside of Pennsylvania.

AVERAGE VALUE

Before the Bituminous Coal Act of 1937 was passed, the most valuable single index of the trend of prices at the mines was the "average value per ton, f. o. b. mines," as given in the familiar annual coal reports of the Bureau of Mines, United States Department of the Interior. This series was referred to in Bureau of Mines reports as representing "bituminous coal," and it covered all coal (other than Pennsylvania anthracite) produced in the United States. It represented the bituminous-coal industry as the term ordinarily was used in the trade and included the lignite of the Dakotas, Texas, and Montana, as well as any small tonnages of hard coal produced outside of Pennsylvania.

With the passage of the Coal Act, the Bureau of Mines relinquished the collection of statistics relating to bituminous coal, effective June 30, 1937, though continuing to compile data regarding lignite and Pennsylvania anthracite. Effective the same date, the Coal Commission became responsible for the compilation of data on bituminous coal, though not attempting to collect data regarding lignite, which was specifically exempted by the act. The records of the Commission (later the Bituminous Coal Division, United States Department of the Interior) relate to all coal other than Pennsylvania anthracite, Virginia semianthracite, and lignite.

To permit comparison of the old and new series, therefore, it is necessary to separate the lignites from the bituminous coals, though for the convenience of the student the combined average for the two is continued in a form as nearly comparable as possible to the old series (see table 24).

A more important change in the two series relates to the treatment of selling expenses. The old Bureau of Mines series of "value at the mines" excluded the selling cost. Reporting operators were asked to state the "Amount received at the mines f. o. b. cars less the selling expense." No details were asked regarding the items included in the value, and no systematic effort was made to follow up the exclusion of selling expenses. It was realized at the time that some producers might find it impractical to exclude selling costs and that some part of the selling expenses of the industry might be included in the results. Nevertheless, the reports were checked for consistency from year to year, the questions were retained in the same form without change, and the results are believed to have been comparable from one year to the next. The new series of the Coal Commission represents the total or gross realization on all coal produced and specifically includes the selling cost.

The two sets of data may not be precisely comparable with respect to coal produced but not sold on the commercial market. In the Bureau of Mines series reporting operators were instructed that the "Value of coal not sold but used by producer, also mine fuel and coal made into coke should be estimated at average prices that might have been received." The instructions of the Coal Commission regarding such items were in effect similar, though given in greater detail.

A comparison of the two series is possible for 1936. In that year the average value per ton on the old (Bureau of Mines) basis amounted to $1.761 per ton for bituminous coal, excluding lignite. The average gross realization, according to data collected by the Coal Commission, was $1.831 per ton. The difference amounts to $0.07 per ton—an amount somewhat less than the average selling expenditures computed per ton of all coal produced, as reported to the Coal Commission. The comparison confirms previous indications that the great majority of operators reporting in earlier years had followed instructions and omitted selling expenses in computing the average value but that some of them had included the selling expense. The change in method of reporting should be kept in mind in comparing the two sets of data. As the reports to the Commission were submitted on a detailed accounting return, and made under oath they are to be accepted. The returns of earlier years, upon a voluntary basis and not in all instances uniform as to treatment of selling costs, seem to have been thoroughly comparable from one year to the next and afford the best available index to the rise and fall of the mine prices received by operators down to 1936.

TABLE 24.—*Trend of average value in the United States of bituminous coal and lignite per ton, f. o. b. mines, 1929–42*

Year	Bituminous coal (subject to regulation under 1937 act[1]	Lignite[2]	Total
Average value per ton less selling cost:			
1929	$1.782	$1.548	$1.781
1930	1.702	1.556	1.701
1931	1.542	1.410	1.541
1932	1.313	1.313	1.313
1933	1.337	1.188	1.336
1934	1.751	1.387	1.749
1935	1.772	1.120	1.767
1936	1.761	1.061	1.756
Average gross realization, selling cost not deducted:			
1936	1.831	[3] 1.061	1.826
1937	1.946	[3] 1.080	1.939
1938	1.955	[3] 1.071	1.947
1939[4]	1.850	1.158	1.845
1940	1.913	[3] 1.156	1.908
1941	2.194	1.237	2.189
1942	2.363	1.364	2.358

[1] Includes all coal produced other than Pennsylvania anthracite and the lignite included in the second column.

[2] North Dakota, South Dakota, and the lignite counties of Montana and Texas.

[3] Figures for 1936–38 and 1940 exclude selling cost as before.

[4] Producers were asked to exclude selling cost in reporting value, but a number of them included such costs.

LABOR STATISTICS

Men employed.—An average of 461,991 men was employed at bituminous-coal mines in 1942, a 1.1-percent increase over the total of 456,981 for 1941 (see fig. 10). Statistics on men employed in 1941 represent annual averages of the number of workers on the rolls on the days when the mines were in operation.

The method used here in calculating employment gives an accurate measure of the working force in the coal industry, but it does not consider the time lost by men on the rolls through intermittent operations. To measure the influence of intermittency upon employment the factor of mine activity as indicated by the average number of days of plant operation was recorded separately. The average number of men employed when the mines were in operation was then used, in conjunction with the average number of days of operation, as a measure of the total volume of employment in the industry.

Days operated.—The average number of days of operation at bituminous-coal mines in 1942 was 246. This represents an increase over the average of 216 days for 1941. All statistics on days of mine operation included in this report are weighted averages, in which the operating time of each mine has been weighted by the number of its employees. Several coal-mining States publish series on the number of days worked that are simple averages of the figures for each reporting mine, regardless of size. As these unweighted averages are likely to be unduly depressed by small mines, which generally operate fewer days than the larger ones, they tend to understate the working time of a typical mine employee.

Man-days of labor.—Only a small proportion of the bituminous-coal-mine operations, however, keep an accurate record of man-days or man-hours worked. Consequently, man-days have been computed by multiplying the number of workers employed by the number of operating days. Although these computations were made for each individual mine, the combined total is necessarily only an approximation.

Until the American coal industry arranges to keep an accurate record of man-days or man-hours of employment all computations of accident rates, daily earnings, and output per man will remain subject to qualification. Meanwhile, the method of multiplying men by days must be accepted as the best available procedure.

Data for 1942 indicate that bituminous-coal-mine employees performed 113,727,282 man-days of labor during the year. Table 17 gives a summary record of men employed, days operated, and output per man per day at bituminous-coal mines, by States, in 1942. Details by counties for 1942 are shown in table 54.

Length of working day.—Table 25 summarizes the replies of mine operators to the question, "Number of hours operated per shift."

The reports of more than 7 hours of work per shift in 1942 consist partly of (1) work for which the operator has included time when the men are entering or leaving the mine, (2) work for which the operator has reported the time of certain employees who work longer than other employees, as in stripping overburden, or (3) operations where work is staggered and two crews of men overlap. There were, however, a number of mines in 1942 where the established day was 8 hours. As shown by the table, most of these were very small. Numerous mines, especially the smaller ones, failed to answer the question.

It was found that 90.5 percent of the men employed were in 7-hour mines and that the weighted average working shift was 7.05 hours.

The established working day does not of itself measure the length of time that men actually work or the time that they are underground, because of the possibility of overtime, because the mine may sometimes shut down before the full day is over, because the miner may go home before the mine stops, and because he spends a considerable time going to and from his place of work underground.

As interpreted in the wage agreements, the 7-hour day means 7 hours of labor at the usual working place, exclusive of any time for lunch and exclusive of the time spent in going from the entrance of the mine to the working place and back again. As noted, these figures represent the operator's statement of the nominal operating day for the mine. They do not purport to represent the time actually worked by the men. On the one hand, they make no allowance for tonnage or piece workers who leave early; on the other hand, they make no allowance for tonnage men who continue at work after the mine as a whole is shut down, or who go into the mine to work on days when the tipple is idle.

TABLE 27.—*Bituminous coal and lignite loaded for shipment by railroads and waterways in the United States, as reported by mine operators, in net tons, in 1942* [1]—Continued

Route	State	Quantity	
		By State	Total for route
WATERWAYS			
Allegheny River	Pennsylvania	1,122,106	1,122,106
Black Warrior River	Alabama	415,186	415,186
Cheat River	Pennsylvania	137,234	137,234
Green River	Kentucky	617	617
Illinois River	Illinois	553,228	553,228
Kanawha River	West Virginia	2,328,631	2,328,631
Monongahela River	Pennsylvania	26,912,826	27,713,681
	West Virginia	800,855	
Muskingum River	Ohio	1,057,672	1,057,672
Ohio River	Kentucky	201,209	579,847
	Ohio	2,784	
	West Virginia	375,854	
Tennessee River	Tennessee	109,823	109,823
Total waterway shipments		34,018,025	34,018,025
Total loaded at mines for shipment by railroads and waterways.		516,832,067	516,832,067
Shipped by truck or wagon		45,154,432	45,154,432
Taken by locomotive tenders at tipple		920,213	920,213
Shipped by conveyor or tram to point of consumption.		7,121,116	7,121,116
Coal used by employees		2,180,077	2,180,077
Used at mine for power and heat		2,708,312	2,708,312
Made into beehive coke at mine		7,776,720	7,776,720
Total production		582,692,937	582,692,937

---

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water. In general, the figures show the quantity of bituminous coal and lignite originated for each railroad and waterway as reported by the mine operators. It must be noted that in 1 year an operator may report coal loaded on the subsidiary railroad and in another year the same operator may report coal loaded on the parent railroad system.

[2] Texas lignite mines shipping over the Missouri-Kansas-Texas, Rockdale, Sandow & Southern, St. Louis Southwestern of Texas, and the Texas Short Line have been included with the International-Great Northern

METHODS OF RECOVERY

[1] Includes Maryland, and Grant, Mineral, and Tucker Counties, W. Va.

[2] For purposes of concealment of individual operators' figures, Montana lignite, with production of 49,138 tons, has been included with Texas lignite.

[3] Includes Colfax County, N. Mex.

[4] Includes Arizona and California, but excludes Colfax County, N. Mex. No production was reported for California.

[5] Includes Idaho. No production was reported for Idaho.

[6] Some coal "Mined by hand" in South Dakota included under "Shot off the solid."

[7] Includes Oregon.

[8] For purposes of historical comparison and statistical convenience, the figures include the output of lignite and of anthracite and semianthracite outside of Pennsylvania.

STRIPPING OPERATIONS

TABLE 31.—*Stripping operations of all types in the butuminous-coal and lignite fields of the United States, by States and Counties, in 1942*

[Returns for mines that recover coal both by stripping and by underground operations do not permit separating men engaged in stripping from those engaged in other work. For this reason, the figures of men employed represent all persons working at these mines, including those underground. The total tons produced by both methods at these mines are also shown]

State and county	Number of strip pits	Number of power shovels			Coal produced (net tons)		Average number of employees				Average number of days mines were active	Number of man-days worked	Average tons per man per day
		Steam	Electric	All others	Mined by stripping	Total at same mines	Underground	Surface: In strip pits	Surface: All others	Total

Grand total	834	199	219	1,020	67,202,663	[4] 25,560	[4] 222	[4] 13.10

[1] Excludes coal produced by underground mining conducted in the same operation.

[2] Includes Colorado and Wyoming.

[3] Includes operations in Alabama, Arkansas, Illinois, North Dakota (lignite), Ohio, Pennsylvania, Washington, and West Virginia in which the output was obtained by both methods. In addition to the 3,680,190 tons produced by stripping, this group of 81 mines obtained 7,243,615 tons by underground methods, their total production by both methods being 10,923,805 tons.

[4] Includes data on underground mining conducted in the same operation.

TABLE 33.—*Summary of operations of power strip pits proper in the bituminous-coal and lignite fields of the United States, by districts, in 1942*

[1] Excludes coal produced by underground mining conducted in the same operation.
[2] Includes Maryland and Grant, Mineral, and Tucker Counties, W. Va.
[3] Included under "Undistributed" to avoid disclosing individual operations.
[4] For purposes of concealment Montana lignite is included with Texas lignite.
[5] Includes Colfax County, N. Mex.
[6] Includes Arizona and California, but excludes Colfax County, N. Mex.
[7] Includes Idaho. No production was reported for Idaho.
[8] Includes Oregon.
[9] Includes operations in districts 1, 2, 3, 4, 6, 7, 10, 12, 14, 21, and 23 in which the output was obtained by both methods. In addition to the 3,680,190 tons produced by stripping, this group of 81 mines obtained 7,243,615 tons by underground methods, their total production by both methods being 10,923,805 tons.
[10] Includes data on underground mining conducted in the same operation.
[11] For purposes of historical comparison and statistical convenience, the figures include the output of lignite and of anthracite and semianthracite outside of Pennsylvania.

[1] Includes Maryland, and Grant, Mineral, and Tucker Counties, W. Va.
[2] Included under "Undistributed."
[3] Includes Colfax County, N. Mex.
[4] Includes Arizona and California, but excludes Colfax County, N. Mex.
[5] Incomplete. Part of total included under "Undistributed."
[6] Includes Idaho. No production was reported for Idaho.
[7] Includes Oregon.
[8] For purposes of historical comparison and statistical convenience, the figures include the output of lignite and of anthracite and semianthracite outside of Pennsylvania.

See footnotes at end of table.

MECHANICAL LOADING

Mechanical loading devices for use in underground bituminous-coal and lignite mines are divided into two clasess: Those that practically eliminate hand-shoveling, which are known as mobile loaders, scrapers, and self-loading conveyors or duckbills; and those that reduce the labor of hand-shoveling, which are known as hand-loaded face conveyors and pit-car loaders.

In 1923, the first year data were recorded on merchanical loading, 60 mines loaded 1,879,726 net tons (0.3 percent of the total underground output) with the aid of mechanical loading devices. In 1933, 10 years later, 283 mines were using loading devices, and 12 percent of the total underground output was mechanically loaded. Since 1933 the proportion of tonnage mechanically loaded has increased each year and in 1942 amounted to 45 percent of the total underground bituminous coal and lignite mined in the United States.

During 1942 mobile loaders, scrapers, and duckbills handled 71 percent of the underground tonnage mechanically loaded, and hand-loaded conveyors and pit-car loaders handled 29 percent.

Detailed statistics on mechanical loading given in the following tables (36 to 44, inclusive) pertain to underground coal mines and do not include strip mines or equipment used for handling coal on the surface. All tonnage figures on coal mechanically loaded include the initial phase of loading only; for instance, if conveyors were used in conjunction with mobile loaders, the tonnage is shown under mobile loading machines and not under conveyors.

Sales of mechanical loading equipment in 1943.—The estimated capacity of mechanical loading equipment sold for underground use in all coal mines was 32 percent less in 1943 than in 1942. This decrease was due to some of the manufacturers devoting a portion of their facilities to war work. Table 36 shows the sales reported, by type of equipment, and the number of manufacturers reporting for 1936–43.

Sales of conveyors to bituminous-coal and lignite mines in 1943 totaled 798 units. The figures for 1942 and 1943 exclude duckbills, which were included in all previous years. Therefore, the figures for 1942 and 1943 are not comparable with those for 1941 or earlier years. By excluding sales of duckbills, some of the overlapping sales of conveyors are eliminated. For instance, in 1941 there were 3,595 conveyors, including those hand-loaded and those equipped with duckbills, in active use at bituminous-coal and lignite mines, as reported by mine operators. By adding 1941 conveyor and duckbill sales of 1,800 units, 5,395 units appeared available for use in 1942, whereas the actual number reported in use by mine operators was 4,103, or 1,292 less. This difference represents idle or worn-out and obsolete equipment, duplications in reporting sales, and a small number of conveyors used in conjunction with mobile loaders.

The number of mobile loaders, scrapers, and conveyors shipped into the various States and groups of States in 1943 and the number of units in actual use in 1942 are shown in table 38. West Virginia received 27 percent of the mobile loaders and 40 percent of the conveyor units sold to bituminous-coal and lignite mines in 1943.

Detailed statistics of mechanical loading in bituminous-coal and lignite mines in 1942, by types of equipment.—During 1942 the approximate percentage of the tonnage loaded by each type of equipment was as follows: Mobile loaders, 69; hand-loaded conveyors, 20; duckbills, 9; pit-car loaders, 1; and scrapers, 1.

Mobile loaders handle more coal than all the other types of mechanical loading devices combined. Where coal is loaded by mobile loaders it is most commonly loaded directly into mine cars, but some tonnage is loaded into shuttle cars or onto conveyors. During 1942, 81 percent of the bituminous coal and lignite handled by mobile loaders was loaded directly into mine cars, 16 percent into shuttle cars, and 3 percent onto conveyors.

During 1942 in underground bituminous coal and lignite mines 2,301 mobile loaders handled 160,300,935 net tons, an average of 69,666 tons per mobile loader per year; scrapers averaged 15,103; pit-car loaders, 6,760; duckbills, 19,476; and hand-loaded face conveyors, 15,542 per year per unit for the same period (see tables 37 and 39).

Mechanical loading, by States.—West Virginia has been the leading producer of mechanically loaded coal since 1939. During 1942 West Virginia produced 70,081,749 net tons of mechanically loaded coal, followed by Pennsylvania with 42,139,366 net tons, Illinois with 41,453,190, Kentucky with 16,931,124, and Ohio with 15,451,347. These five States produced 80 percent of the total output of underground mechanically loaded bituminous coal in the United States in 1942.

Detailed data by States, on the number of mines amd machines and the production of mechanically loaded coal compared with total production at mines using mechanical loading devices are given in table 40, and similar data by Coal Act districts are shown in table 41. Comparative changes in underground mechanical loading in 1941–42, by States and Coal Act districts, are shown in tables 42 and 43.

Table 44 gives bituminous coal and lignite mined by stripping compared with underground hand-loaded and machine-loaded tonnage by States, for 1942.

TABLE 36.—*Units of mechanical loading equipment sold to bituminous-coal and lignite mines for underground use in the United States, as reported by manufacturers, 1936-43, inclusive*

[1] Includes those mines in which all of the tonnage mechanically loaded was obtained with machines that substantially eliminate hand shoveling; that is, mobile loaders, scrapers, and conveyors equipped with duckbills or other self-loading heads. Some mines in this class also use conveyors in conjunction with mobile loaders to perform the initial phase of transportation.

[2] Includes those mines in which all the tonnage mechanically loaded was obtained with hand-loaded conveyors and pit-car loaders.

[3] Number of units.

[4] Includes Maryland and Grant, Mineral, and Tucker Counties, W. Va.

[5] Included under "Undistributed" to avoid disclosing individual operations.

[6] Incomplete. Part of total included under "Undistributed."

[7] Includes Colfax County, N. Mex.

[8] Includes Arizona and California, but excludes Colfax County, N. Mex.

[9] Includes Idaho. No production was reported for Idaho.

[10] Includes Oregon.

[11] For purposes of historical comparison and statistical convenience, the figures include the output of lignite and of anthracite and semianthracite outside of Pennsylvania.

TABLE 41.—*Mechanical loading underground in bituminous-coal and lignite mines in the United States, by States, in 1942*

[This table includes all soft-coal mines that produced any part of their tonnage with the aid of mechanical loading devices in 1942]

State	Number of mines				Number of machines					Production mechanically loaded (net tons)			Total production at mines using mechanical loading devices (net tons)			
	Using loading machines only [1]	Using conveyors only [2]	Using both loading machines and conveyors	Total	Mobile loading machines	Scrapers	Conveyors equipped with duckbills or other self-loading heads	Pit-car loaders	Hand-loaded conveyors [3]	Loaded by machines [1]	Handled by conveyors [2]	Total	Mines using loading machines only [1]	Mines using conveyors only [2]	Mines using both loading machines and conveyors	Total

[1] Includes Maryland and Grant, Mineral, and Tucker Counties, W. Va.

[2] Included under "Undistributed."

[3] Incomplete. Part of total included under "Undistributed."

[4] For purposes of concealment of individual operators' figures, Montana lignite with production of 49,138 tons has been included with Texas lignite.

[5] Includes Colfax County, N. Mex.

[6] Includes Arizona and California, but excludes Colfax County, N. Mex. No production was reported for California.

[7] Includes Idaho. No production was reported for Idaho.

[8] Includes Oregon.

[9] For purposes of historical comparison and statistical convenience, the figures include the output of lignite and of anthracite and semianthracite outside of Pennsylvania.

MECHANICAL CLEANING

In 1906, when the first statistics were recorded on bituminous-coal cleaning, 9,251,946 net tons were cleaned by wet methods at the mines. Pneumatic cleaning was introduced in 1919, but the first statistics begin with 1927, when 3,650,584 net tons were cleaned at the mines.

In 1927, the first year complete data were collected on mechanical cleaning of bituminous coal, 27,692,047 net tons were cleaned, which was 5 percent of the total output. This percentage has increased each year, and in 1942 amounted to 24, or 142,187,346 net tons of clean coal.

Tables 46, 47, 50, 51, 52, and 53 include mechanical cleaning data on all coal mined in the United States except Pennsylvania anthracite. Tables 49 and 50 are upon the same basis but do not include consumer-operated plants. There are no mechanical cleaning plants at lignite mines.

Consumer-operated plants include plants owned by steel companies which receive coal from various mines (but usually from affiliated companies), clean it, and then consume it directly at the plant.

Table 46 compares bituminous coal cleaned in 1939–42, inclusive, by method of cleaning. Both wet and pneumatic methods increased in 1942 over 1941.

Mechanical cleaning, by types of equipment.—The tonnage of bituminous coal cleaned by wet-washing methods reached 121,999,858 net tons in 1942—an increase of 21 percent over 1941. The quantity cleaned by pneumatic methods was 20,187,488 net tons—an increase of 18 percent over 1941.

Table 47 compares the number of cleaning plants and the net tons of cleaned coal, by types of equipment, for 1941 and 1942. During 1942, 406 wet-washing and 84 pneumatic cleaning plants were in operation. Fifty-two tipples used both wet and dry methods at the same plant; deducting these duplications gives a net total of 438 plants that cleaned coal in 1942 compared with 417 in 1941.

Wet methods of cleaning coal include piston- or common-type jigs, Baum-type jigs, concentrating tables, launders and upward-current classifiers, and combinations of jigs with concentrating tables and jigs with launders or upward-current classifiers. Baum-type jigs cleaned approximately 42 percent of the coal cleaned by wet methods during 1942.

Pneumatic methods of coal cleaning include air tables, air flow, air sand, and any combinations of these three methods. During 1942, air tables cleaned 59 percent of the coal cleaned by pneumatic methods.

Table 48 lists the total production in 1941 and 1942 at bituminous-coal mines that have cleaning plants, by types of equipment. This table shows that 218,073,891 net tons were produced at mines with cleaning plants in 1942, but the cleaned coal obtained at these mines totaled 131,397,597 net tons (see table 52) or 60 percent of the total produced. The remainder of the output (40 percent) presumably represents the larger sizes, which are generally hand-picked.

Coal cleaning, by States.—In volume of total tonnage of bituminous coal mechanically cleaned in 1942, Pennsylvania led; West Virginia, Illinois, Alabama, and Indiana followed in the order named. These five States supplied 119,309,228 tons (84 percent) of the total. Table 50 shows the number of plants in operation, net tons of clean coal, and percentage of State output mechanically cleaned in 1941 and 1942. Table 51 shows similar data by Coal Act districts.

Relation between raw coal, clean coal, and refuse.—For every 100 tons of raw coal cleaned at the mines during 1942, 86.9 tons of clean merchantable coal, on an average, were obtained, and 13.1 tons of refuse were discarded. Tables 52 and 53 show total production of mines with cleaning plants and results of cleaning operations by States and Coal Act districts, respectively.

Methods of mining at mines served by cleaning plants.—Mechanical loading, both in underground mines and strip pits, appears to be closely related to mechanical cleaning. Table 49 shows the mining methods at mines that have cleaning plants. Production of coal from strip mines in 1942 was 67,202,663 tons (see table 44); 28,597,289 tons (43 percent) came from strip mines having mechanical cleaning tipples. 232,902,920 tons of underground coal were loaded mechanically in 1942, of which 118,917,178 tons (51 percent) passed through tipples equipped with mechanical cleaning devices. Hand-loaded underground coal production in 1942 totaled 282,587,354 tons, of which 25 percent passed through tipples equipped with cleaning plants.

TABLE 46.—*Bituminous coal mechanically cleaned by wet and pneumatic methods, in the United States, in net tons of clean coal, 1939–42*

Method of cleaning	1939	1940	1941	1942	Change, 1942 from 1941 (percent)
By wet methods:					
At mines	60,933,898	78,539,869	91,126,091	111,210,109	+22.0
At consumer-operated cleaning plants	6,800,587	8,750,220	9,251,543	10,789,749	+16.6
Total wet methods	67,734,485	87,290,089	100,377,634	121,999,858	+21.5
By pneumatic methods	11,694,941	14,979,664	17,161,888	20,187,488	+17.6
Grand total	79,429,426	102,269,753	117,539,522	142,187,346	+21.0

TABLE 47.—*Bituminous coal cleaned in the United States, by types of equipment in actual operation, 1941–42*

[Coal cleaned and plants operated by consumers at central washeries in Colorado and Pennsylvania are included]

Type of equipment	Plants in operation		Net tons of clean coal		Percent cleaned by each type	
	1941	1942	1941	1942	1941	1942
Wet methods:						
Jigs	202	220	53,286,566	66,875,931	45.3	47.0
Concentrating tables	13	16	2,510,186	3,138,365	2.2	2.2
Jigs in combination with concentrating tables	20	15	4,364,220	4,366,100	3.7	3.1
Jigs in combination with launders and upward-current classifiers	11	14	5,446,245	5,594,983	4.6	3.9
Launders and upward-current classifiers	135	141	34,770,417	42,024,479	29.6	29.6
Total wet methods	381	406	100,377,634	121,999,858	85.4	85.8
Pneumatic methods	80	84	17,161,888	20,187,488	14.6	14.2
Grand total	[1] 461	[1] 490	117,539,522	142,187,346	100.0	100.0

[1] Plants using both wet and pneumatic methods totaled 44 in 1941 and 52 in 1942.

TABLE 48.—*Total production of all coal at bituminous mines in the United States having cleaning plants, in net tons, 1941–42*

[Does not include any estimate for mines that may ship to consumer-operated plants]

Type of equipment	1941	1942	Change, 1942 from 1941 (percent)
Wet methods:			
Jigs	85,752,968	103,929,379	+21.2
Concentrating tables	1,927,109	2,795,456	+45.1
Jigs in combination with concentrating tables	5,097,435	4,855,537	−4.7
Jigs in combination with launders and upward-current classifiers	8,325,444	8,948,388	+7.5
Launders and upward-current classifiers	69,351,140	82,712,948	+19.3
Total wet methods	170,454,096	203,241,708	+19.2
Pneumatic methods	45,471,216	53,367,701	+17.4
Grand total	215,925,312	256,609,409	+18.8
Less duplication [1]	30,457,143	38,535,518	+26.5
Net total	185,468,169	218,073,891	+17.6
United States total production [2]	514,149,245	582,692,937	+13.3
Percent produced at mines having cleaning plants	36.1	37.4	

[1] Mines using both wet and pneumatic methods.

[2] For purposes of historical comparison and statistical convenience, the figures include the output of lignite and of anthracite and semianthracite outside of Pennsylvania. There are no mechanical cleaning plants at lignite mines.

TABLE 49.—*Method of mining at bituminous-coal mines in the United States served by cleaning plants, 1939–42*

[Does not include any estimate for mines that may ship to consumer-operated plants]

Method of mining in use	Total production from mines that move coal to cleaning plants (net tons) [1]				Change, 1942 from 1941 (percent)
	1939	1940	1941	1942	
Mined from strip pits	17,960,049	20,029,770	24,773,543	28,597,289	+15.4
Mechanically loaded underground	53,495,851	66,148,465	93,373,789	118,917,178	+27.4
Hand-loaded underground	61,857,850	75,557,899	67,320,837	70,559,424	+4.8
Total	133,313,750	161,736,134	185,468,169	218,073,891	+17.6

[1] Based upon shipping weights and includes some marketable coal that did not pass through cleaning plants.

TABLE 50.—*Bituminous coal mechanically cleaned by wet and pneumatic methods in the United States, by States, 1941–42*

[Coal cleaned and plants operated by consumers at central washeries in Colorado and Pennsylvania are included]

[1] Included in "Undistributed."

[2] Includes some coal mined in Pennsylvania and cleaned in Ohio and a small tonnage mined in West Virginia and cleaned at a consumer-operated plant in Pennsylvania.

[3] Includes some coal mined in West Virginia and cleaned in Ohio.

[4] Represents 44 plants using both wet and pneumatic methods of cleaning plus 373 plants using only 1 cleaning method.

[5] Represents 52 plants using both wet and pneumatic methods of cleaning plus 386 plants using only 1 cleaning method.

TABLE 51.—*Bituminous coal mechanically cleaned by wet and pneumatic methods in the United States, by districts, 1941–42*

[Districts as defined in the Bituminous Coal Act of 1937 and modifications thereto. Coal cleaned and plants operated by consumers at central washeries in Colorado and Pennsylvania are included]

[1] Based upon shipping weights, and includes some marketable coal that did not pass through cleaning plants.

[2] Includes Maryland, and Grant, Mineral, and Tucker Counties, W. Va.

[3] Included under "Undistributed."

[4] Includes some coal that was mined in Pennsylvania and cleaned in Ohio.

[5] Includes some coal that was mined in West Virginia and cleaned in Ohio.

[6] Incomplete. Part of total included under "Undistributed"

[7] Includes Colfax County, N. Mex.

[8] Includes Arizona and California, but excludes Colfax County, N. Mex.

[9] Includes Idaho.

[10] Includes Oregon.

[11] Includes all mechanical cleaning other than washeries operated by consumer steel companies.

[12] Includes central washeries in Colorado and Pennsylvania operated by consumer steel companies.

[13] For purposes of historical comparison and statistical convenience, the figures include the output of lignite and of anthracite and semianthracite outside of Pennsylvania. There are no mechanical cleaning plants at lignite mines.

DETAILED STATISTICS, BY STATES AND COUNTIES

Detailed production and employment statistics are given in table 54 for each coal-producing county in the United States from which three or more operators submitted reports for 1942. Statistics on counties with less than three reporting producers have been combined with data for other counties in the same State to avoid disclosing individual returns, unless permission to publish has been granted by the operators. Production of mines on the border between two States has been credited to the State from which the coal is extracted rather than that in which the tipple is situated. If the coal is mined from lands in both States, the tonnage has been apportioned accordingly.

In this series the reported production is classified according to the principal methods of distribution or use. Beginning with 1932, the series was expanded to include data on the growing volume of coal moving from mine to consumer by truck. For 1933–36 this tonnage was shown as "commercial sales by truck or wagon." In 1937 this tonnage was shown as "truck deliveries, including local sales." (See Minerals Yearbook, 1939, p. 813.) In 1938 the truck tonnage was shown as "shipped by truck or wagon." The truck figures for 1933 to 1936, inclusive, and 1938 to 1942, inclusive, are reasonably comparable.

The data in this report, like those published for many years by the Bureau of Mines, relate only to mines with an annual output of 1,000 tons or more. This fact should be borne in mind when the statistics in this report are compared with similar data compiled by State mine departments. Differences arise largely from variations in coverage of the State reports, some of which include data for all mines, regardless of size, and others only data for mines employing more than a specified minimum number, which ranges from 2 to 10 men. To meet the administrative demand for statistics on mines with an annual output of less than 1,000 tons per year, data are shown for the small mines in table 55. The production in table 55 is not included in the total output for the United States as this would upset the comparability of the statistical series.

Because of a change in the method of reporting, the statistics of average production per man per day for 1932 to 1936 and 1938 to 1941 are not precisely comparable with those for earlier years. Before 1932 they were based upon the calculated number of man-shifts, obtained by multiplying the average number of men employed at each mine by the number of days worked at the mine. Since 1932 operators have been asked to make a special report of the number of man-shifts actually worked, if possible. The number of operators able to furnish this information has been small, although it is increasing from year to year. These reports were utilized to improve the accuracy of the record. Otherwise, the man-shifts were calculated by multiplying the number employed underground and on the surface by the number of days worked by the mine and tipple, respectively.

TABLE 54.—*Production, value, employment, days active, man-days, and output per man per day at bituminous-coal and lignite mines in the United States, by States and counties, in 1942*

[Exclusive of mines producing less than 1,000 tons]

County	Disposition of coal produced (net tons)					Average value per ton [3]	Average number of employees				Average number of days mines were active	Number of man-days worked	Average tons per man per day
	Loaded for shipment by rail or water [1]	Shipped by truck or wagon (excluding coal used by mine employees)	Used by mine employees, taken by locomotive tenders at tipple, or other uses at mine [2]	Used at mine for power and heat or made into beehive coke at mine	Total quantity		Underground	Surface		Total			
								In strip pits	All others

---

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by truck to railroad siding for shipment by rail, and hauled by truck to waterway for shipment by water.

[2] Includes coal transported from mines to points of use by conveyor or tram.

[3] Value received or charged for coal f. o. b. mine, including selling cost. (Includes a value for coal not sold but used by producer, such as mine fuel and coal coked [not coke] as estimated by producer at average prices that might have been received if such coal had been sold commercially.)

[4] Includes 26,756 tons made into beehive coke at mines in Jefferson County, Ala., in 1942.

[5] No coal was made into beehive coke at mines in 1942.

[6] Includes 136,905 tons made into beehive coke at mines in Las Animas County, Colo., in 1942.

[7] "Other counties" in Illinois include Bond, Jefferson, Logan, Marion, Marshall, Tazewell, Wabash and Will.

[8] Much of the output is obtained from strip pits and by use of mechanical loading devices, in which types of operations production per man per day is large.

[9] Production of Alston Coal Co. (Alston mine) and Hume-Sinclair Coal Mining Co. (Foster mine) is credited to Missouri, and production of Hume-Sinclair Coal Mining Co. (Tiger mine) is credited to Kansas.

[10] The output is obtained chiefly from strip pits in which the production per man per day is large.

[11] Includes 1,897 tons made into beehive coke at mines in Jackson County, Ky., in 1942.

[12] In Montana and South Dakota some lignite "Loaded for shipment" is included in "Shipped by truck or wagon." In Montana some "Used by employees" is included with "Used at mine for power and heat." In North Dakota some lignite "Made into briquets" is included with "Other uses at mine."

[13] Includes coal made into beehive coke at mines in the following counties in Pennsylvania in 1942: Cambria, 124,182 tons; Fayette, 4,412,417 tons; Greene, 4,403 tons; Indiana, 347,398 tons; Westmoreland, 1,600,048 tons; grand total, 6,488,448 tons.

[14] Includes 4,277 tons made into beehive coke at mines in Grundy County, Tenn., in 1942.

[15] Includes 43,674 tons made into beehive coke at mines in Carbon County, Utah, in 1942.

[16] The output is obtained chiefly by the use of mechanical loading devices in which type of operation the production per man per day is large.

[17] Includes 563,356 tons made into beehive coke at mines in Wise County, Va., in 1942.

[18] Includes coal made into beehive coke at mines in the following counties in West Virginia in 1942: Fayette, 345,406 tons; Monongalia, 34,539 tons; Preston, 130,476 tons; Randolph, 986 tons; grand total, 511,407 tons.

SUMMARY OF SMALL MINES

TABLE 55.—*Summary of data on mines in the United States producing less than 1,000 tons a year, by States and Districts, in 1942* [1]

[Figures compiled from schedules actually received and supplemented by State mine inspectors' reports where available. It was not possible to obtain complete coverage. The data shown in this table are not included in the other parts of this report.]

	Number of active mines	Total production	Average value per ton	Average number of employees	Average number of days mines were active	Number of man-days worked	Average tons per man per day
By States:

---

[1] Data on small lignite mines in Montana, North Dakota, South Dakota, and Texas not available.
[2] Includes Georgia and North Carolina.
[3] For boundaries of districts, see Bituminous Coal Act of 1937 and modifications thereto.

STATISTICS ON LIGNITE IN 1942 [1]

PRODUCTION

The statistics in this chapter on the lignite industry in the United States were compiled from annual reports received from producers of lignite in the areas mapped as lignite in Geological Survey Professional Paper 100–A, The Coal Fields of the United States. Subbituminous coal, sometimes called black lignite, is not included in these statistics.

The production of lignite in 1942 totaled 2,930,661 net tons, exclusive of some small mines that produced less than 1,000 tons. Output in 1942 showed a slight increase over the 2,775,832 tons produced in 1941. The average value per ton was $1.36 in 1942 compared with $1.24 in 1941. The total employees in 1942 numbered 1,490 against 1,644 in 1941; and the average output per man per day, based upon calculated man-days, for the same periods was 9.84 and 9.54 tons, respectively. The length of the working day in most of the mines was 8 hours. Some mines showed a 7-hour day on their reports to the Bureau and a few a 9-hour day; some of the small mines did not reply to this question. No labor disturbances were reported.

As for many years in the past, North Dakota was the chief producer of lignite in 1942, followed in order by Texas, South Dakota, and Montana. The North Dakota output comprised 87 percent of the total production, that of Texas 10, and the outputs of South Dakota and Montana, taken together, 3 percent.

The following tables contain detailed statistics for lignite in 1942. Statistics of the lignite industry in 1943 were not available for publication in this chapter but may be obtained in mimeographed form upon request to the Coal Economics Division of the Bureau of Mines.

TABLE 56.—*Summary of production, value, men employed, days operated, man-days of labor, and output per man per day at lignite mines in the United States in 1942, by States*

	North Dakota	Texas	South Dakota	Montana (1)	Total
Production (net tons):					
Loaded at mines for shipment	1,882,107	286,110	(2)	(2)	2,168,217
Commercial sales by truck or wagon	525,118	1,597	[2] 53,415	[2] 48,990	629,120
Used by employees, taken by locomotives at tipple, and other uses	[3] 94,974		105	[4] 148	95,227
Used at mines for power and heat	34,817	3,262	18	(4)	38,097
Total production: 1942	2,537,016	290,969	53,538	49,138	2,930,661
1941	2,308,888	337,326	70,825	58,793	2,775,832
Value:					
Total: 1942	$3,554,000	$246,000	$104,000	$93,000	$3,997,000
1941	$2,937,000	$284,000	$108,000	$105,000	$3,434,000
Average per ton: 1942	$1.40	$0.85	$1.94	$1.89	$1.36
1941	$1.27	$0.84	$1.52	$1.79	$1.24
Number of employees:					
Underground	491	130	11	51	683
Surface (including strip pits)	693	43	40	31	807
Total employees: 1942	1,184	173	51	82	1,490
1941	1,275	202	69	98	1,644
Average number of days mines operated:					
1942	205	194	198	143	200
1941	177	180	174	174	177
Man-days of labor: 1942 [5]	242,581	33,483	10,118	11,722	297,904
Average output per man per day (tons): 1942 [5]	10.46	8.69	5.29	4.19	9.84

[1] Includes output of Custer, Dawson, McCone, Richland, Roosevelt, Sheridan, and Valley Counties.
[2] Some "Loaded at mine for shipment" included in "Commercial sales by truck or wagon."
[3] Includes some lignite "made into briquets."
[4] Some colliery fuel is included in "Other uses."
[5] Based upon calculated number of man-days.

---

[1] Compiled by J. A. Corgan and M. I. Cooke.

TABLE 57.—*Production, value, men employed, days operated, man-days of labor, and output per man per day at lignite mines in the United States in 1942, by States and counties*

County	Total tons produced (net tons)	Value: Total (thousand dollars)	Value: Average per ton	Total number of employees	Man-days of labor [1]	Average number of days mine operated	Average tons per man per day [1]

[1] Based upon "calculated" man-days.
[2] Output is obtained chiefly from strip pits in which the production per man per day is large.

METHODS OF RECOVERY

TABLE 58.—*Lignite mined by different methods in the United States in 1942, by States, in net tons*

State	Mined by hand	Shot off the solid	Cut by machines [1]	From strip pits	Total
Montana	[2] 18, 807	[2] 229, 737	4, 846	[2] 86, 717	49, 138
North Dakota	5, 066	147, 387	669, 074	1, 715, 489	2, 537, 016
South Dakota	(3)	[3] 4, 362		49, 176	53, 538
Texas	(2)	(2)		(2)	290, 969
Total	23, 873	381, 486	673, 920	1, 851, 382	2, 930, 661

[1] A total of 25 machines was used—16 "permissible" and 9 other types.
[2] Montana includes Texas.
[3] Mined by hand included under "Shot off the solid."

NUMBER AND SIZE OF LIGNITE MINES

For 1942 the Bureau of Mines received reports from 173 lignite mines (exclusive of some mines producing less than 1,000 tons a year). Six mines produced 200,000 to 500,000 tons each, and the output of these mines amounted to 64 percent of the total production; 2 reported production from 100,000 to 200,000 tons and supplied 10 percent of the total output; 2 mines reported an output of 50,000 to 100,000 tons each and contributed 6 percent of the total tonnage; 15 mines in the 10,000- to 50,000-ton class reported 11 percent of the total production; and 148 mines producing less than 10,000 tons each furnished 9 percent of the total output of the industry. The greatest number of mines were located in North Dakota, which State had 141. Montana was next in order with 16 mines; South Dakota and Texas followed with 11 and 5, respectively. In the field as a whole the classification by size of output in 1942 is given in table 59.

TABLE 59.—*Number and production of lignite mines, classified by size of ouput, in 1942*

Classes	Mines		Production		
	Number	Percent	Total (net tons)	Average per mine (net tons)	Percent
1. 200,000-500,000 tons	6	3.4	1,865,461	310,910	63.7
2. 100,000-200,000	2	1.2	298,466	149,233	10.2
3. 50,000-100,000	2	1.2	176,124	88,062	6.0
4. 10,000-50,000	15	8.7	311,428	20,762	10.6
5. Under 10,000	148	85.5	279,182	1,886	9.5
Total	173	100.0	2,930,661	16,940	100.0

STRIPPING OPERATIONS

The production of lignite from strip pits in 1942 amounted to 1,851,382 tons—63 percent of the total output of the industry. As for many years in the past, most of the stripping was done in North Dakota, which produced 1,715,489 tons by that method. This represented 93 percent of all strip-pit production and 59 percent of the total tonnage produced by the lignite industry. The output from stripping operations in Texas, Montana, and South Dakota was only 135,893 tons. The number of men employed in stripping operations was 645, with an average output per man per day of 14.69 tons, and the average number of days worked was 196.

Detailed statistics for stripping operations in the lignite industry in 1942 are given in table 60.

TABLE 60.—*Summary of stripping operations that produced lignite in the United States in 1942, by States*

State	Number of strip pits [1]	Number of shovels, drag line excavators, and coal-loading machines [2]	Coal produced (net tons)		Total value at mines (thousand dollars)	Average value per ton	Number of employees				Average number of days mines operated	Man-days of labor [3]	Average tons per man per day [3]
			Mined by stripping	Total at same mines			Underground	Surface		Total			
								In strip pits	All others				
Montana and Texas	5	8	86,717	86,717	$58	$0.67	----	46	2	48	102	4,875	17.79
North Dakota	63	49	1,715,489	1,723,013	2,355	1.37	13	386	161	560	202	113,306	15.21
South Dakota	6	6	49,176	49,176	94	1.91	----	33	4	37	227	8,384	5.87
Total	74	63	1,851,382	1,858,906	2,507	1.35	13	465	167	645	196	126,565	14.69

[1] Includes some pits in which the stripping is done by hand.

[2] In some cases the same equipment was used for stripping or excavating and for loading the coal; this duplication has been eliminated. In some cases the coal was excavated by machine and loaded by hand.

[3] Based upon calculated man-days.

IMPORTS AND EXPORTS

REVIEW OF 1943

The heavy demand for anthracite continued throughout 1943, and the industry succeeded in producing more anthracite than in any year since 1930, despite loss in manpower, labor disturbances, floods, and difficulty in obtaining equipment and supplies. The output of 60,644,000 tons, however, was not sufficient to meet the demand created by shortages of other space-heating fuels, the requests from Canada for large tonnages, and the increased needs occasioned by the migration of great numbers of people into the highly industrialized New England and Middle Atlantic States. In January 1943 the operators and miners agreed to extend the work week from 5 to 6 days, thereby effecting a considerable increase in the production of anthracite for the year. In a further attempt to meet the demand during the 1943–44 winter, the miners worked 7 days a week in February 1944, and the additional tonnage obtained on the seventh day helped to alleviate the shortage.

From May 1 to October 12, 1943, all anthracite mines were operated under the control of the Federal Government because of unsettled labor conditions occasioned by the absence of a contract between the anthracite producers and the United Mine Workers of America to supersede the one that expired April 30. On November 1, for the same reason, the President issued a second order directing the Secretary of the Interior to take immediate possession of the mines. At the close of the year the mines were still operating under direction of the Government. The Bureau of Mines estimates that stoppages of work in the Pennsylvania anthracite mines in 1943 resulted in a production loss of 5,700,000 net tons. Had it not been for this loss, it is believed that the output of anthracite in 1943 would have met requirements.

The Bureau of Mines worked closely with the Solid Fuels Administration for War in compiling detailed statistical data relating to distribution, production, consumption, utilization, and market requirements for anthracite. The Solid Fuels Administration for War based its program for the equitable distribution of anthracite upon these statistics.

The output of anthracite from "bootleg" holes declined from 5,000,000 net tons in 1941 to 1,912,000 tons in 1943. The decline may be attributed largely to the efforts of the Anthracite Committee to eliminate this unlawful business, the induction of young men into the armed forces, and opportunities for employment in legitimate industry.

Anthracite Industries, Inc., through its laboratory at Primos, Pa., greatly expanded its program embracing fundamental product research and development work on new and improved equipment for burning anthracite.

Funds amounting to $450,000, which were authorized by an act of Congress (S. 357) for the erection of a research laboratory in the anthracite region, will not be available until hostilities cease. Investigations and researches to be conducted through facilities thus afforded will relate particularly to the mining, preparation, and utilization of anthracite and to safety, health, and sanitation in mining operations.

The Anthracite Tidewater Emergency Bureau, established at New York in May 1942 by anthracite producers, wholesalers, and railroads delivering at tidewater ports, continued to function effectively in 1943 in expediting car movement and in arranging for the use of tidewater facilities. The Bureau compiled statistics concerning cars of anthracite standing at tidewater piers and endeavored to bring about more efficient utilization of railroad equipment, boats, and barges engaged in transporting coal at tidewater.

Definition of Pennsylvania anthracite industry.—Based upon differences in composition and characteristics of the product, trade practice and historical usage recognize two major divisions in the coal industry of the United States—bituminous coal and Pennsylvania anthracite. Anthracite and semianthracite are mined also in parts of Virginia, Arkansas, and Colorado and in New Mexico. Locally these coals represent distinct and important industries, but the tonnages involved are small and for statistical convenience usually are grouped with the totals of the bituminous-coal industry.

The Pennsylvania anthracite industry, as here defined, includes all nonbituminous fields of that State. Trade usage commonly includes the output of the Bernice Basin in Sullivan County with Pennsylvania anthracite, although the coal of this basin is classified officially as semianthracite.

Statistical trends.—Tables 1 and 2 present pertinent statistical data on the Pennsylvania anthracite industry.

TABLE 1.—*Statistical trends of Pennsylvania anthracite industry, 1939–43*

	1939	1940	1941	1942	1943
Production:					
Loaded at mines for shipment:					
Breakers net tons	[1] 43,660,662	[1] 43,800,127	46,864,422	51,173,756	[1] 50,812,873

[13] Computed from weekly quotations from trade journals. Figures represent circular prices quoted on white ash by leading anthracite-producing companies.

[14] Bureau of Labor Statistics.

The war and anthracite.—Shortages of competitive fuels and migration of war workers into urban areas of the New England and Middle Atlantic States were responsible for the strong demand for Pennsylvania anthracite in those areas in 1943. In addition to increased requirements for space heating, large quantities were needed by railroads, utilities, industrial plants, and the United States armed forces. Although the industry could not meet requirements, it increased its output over 1942 by 0.5 percent despite the labor shortage, difficulty in obtaining equipment and supplies, and labor disturbances that were estimated to have cost the industry 5,700,000 tons of coal.

In addition to the increased demands in this country, the industry shipped large quantities of anthracite to Canada to substitute for other space-heating fuels, especially gas and oil, the use of which was restricted sharply in that country. Exports, virtually all of which went to Canada, increased from 2,668,000 net tons in 1940 to 4,439,000 tons in 1942. Exports in 1943 totaled 4,139,000 net tons. About 80 percent of the coal shipped to Canada consists of Pea and larger sizes; these sizes are used almost exclusively in Canada for space-heating purposes.

In April 1943 the President abolished the Office of Solid Fuels Coordinator for War by executive order and established within the United States Department of the Interior the Solid Fuels Administration for War, with the Secretary of the Interior as Administrator. This agency and its immediate predecessors were created to handle problems relating to the production, distribution, consumption, and utilization of both anthracite and bituminous coal. Early in 1943 it was apparent that unless available supplies of anthracite were distributed equitably serious area shortages would occur. As an aid to a distribution program the Bureau of Mines, in cooperation with industry representatives and the Solid Fuels Administration for War, collected data from producers and wholesalers of anthracite which showed in detail shipments of anthracite in the coal year April 1, 1942, to March 31, 1943, to destinations in the United States and Canada. From these data, the Solid Fuels Administration for War allocated anthracite to many localities to relieve area shortages.

The Bureau of Mines compiled detailed monthly statistics, also required by Solid Fuels Administration for War, from producers and wholesalers of anthracite.

Anthracite Committee.—The Anthracite Committee, representing operators whose production comprised a large part of the total output of the industry, was particularly active in matters requiring statistics on current production, employment, and other pertinent phases of the industry. Members of the committee represented the producers in various matters before the Office of Price Administration, Solid Fuels Administration for War, and other Government agencies. The committee kept in close contact with the illicit mining industry and made every effort to alleviate this unfavorable economic and social problem.

Anthracite Institute.—Representatives of the Anthracite Institute cooperated with producers of other solid fuels, representatives of the transportation industry, labor interests, and manufacturers of solid-fuels equipment in opposing the extension of natural-gas pipe lines into the principal anthracite markets. The institute expanded its information services considerably to keep the operators apprised of Government regulations, freight rates, State and Federal legislation, and many other pertinent matters of interest to the anthracite industry.

Sales of anthrafilt, the specially prepared anthracite sponsored by the Anthracite Institute and used for filtering, increased 44 percent for the first 9 months of 1943 compared with the same period in 1942. Anthrafilt is used extensively throughout the United States and many foreign countries in filtering boiler-plant water, in water used for swimming pools, and in municipal plants filtering water for drinking and other purposes. Many war plants and other closely allied industries are using anthrafilt in various filtering operations.

Anthracite Industries, Inc.—Anthracite Industries, Inc., with the largest personnel of coal scientists and technicians in its history, has enlarged its scope of research activities. A program conducted at its laboratory (Primos, Pa.) covers research and development work in the design of new anthracite-burning equipment and the development of auxiliary equipment to improve the efficiency and convenience of anthracite-burning equipment now in use. Manufacturers of coal-burning equipment and regulatory devices are encouraged to cooperate with the laboratory. With new and improved heating equipment, the anthracite industry will be in a more favorable position to compete successfully with other fuel industries in the post-war period. The expanded research activities are in addition to current work assisting real estate concerns, the plumbing trade, and Government agencies interested in the proper equipment and methods for burning anthracite.

Labor.—The labor disturbance that began late in December 1942, when 19,000 men went on strike in the Wyoming region, ended January 19, 1943, when the President ordered the miners to resume work. Details of this strike are given in Minerals Yearbook, 1942.

To meet increased demands for anthracite, the operators and miners agreed to extend the workday week from 5 to 6 days, contingent upon an increase of maximum prices of anthracite by the Office of Price Administration to compensate for increased costs occasioned by lengthening of the work week. The price increase of approximately 50 cents a ton was authorized, effective January 9, 1943, and within a few days the miners commenced the 6-day work week.

Representatives of the anthracite producers and United Mine Workers of America were unable to agree on terms of a contract to supersede the one that expired April 30, 1943. In the absence of an agreement the mine workers failed to report for work on May 1. To protect the interests of the Nation at war the President authorized and directed the Secretary of the Interior to take immediate possession of all anthracite mines in which a strike or stoppage occurred, together with all real and personal property, franchises, rights, facilities, funds, and other assets used in connection with operation of the mines and to operate or direct the operation of the mines in such manner as necessary for the successful prosecution of the war. In a radio address, May 2, the President requested that the miners report to work immediately. On May 4 the miners returned to work, and the producers and representatives of the workers agreed to an extension of the contract for a 15-day period ended May 18; on that date a further extension was made through May 31. On June 1 the miners again failed to report for work, returning at the request of the President on June 7, when another extension of the contract was made to

June 20. The mine workers, having again failed to report to work on June 20 when the contract extension expired, were instructed by their leaders to return to work on June 22 and to resume production under direction of the United States Government until midnight October 31, 1943; however, the mines did not swing into full production until July 5.

On October 12 the Federal Government released to private owners the anthracite mines remaining under Government control, taking possession of them again on November 1 in accordance with an order of the President who, in view of the failure of the miners to report to work on that date, directed the Secretary of the Interior to arrange a working agreement with the United Mine Workers of America. An agreement was reached November 3, 1943, and at the close of the year the mines were still operating under this agreement.

Research.—An act of Congress (S. 357) providing for the establishment and operation of a research laboratory in the Pennsylvania anthracite region was approved by the President December 18, 1942. The laboratory, to be established, equipped, and maintained by the Secretary of the Interior, acting through the Bureau of Mines, will be a center of information and assistance in matters pertaining to conserving resources; more efficient mining, preparation, and utilization of anthracite; the solution of economic problems; safety, health, and sanitation in mining operations; and other matters relating to problems of the anthracite industry. The act authorized an appropriation of $450,000 for the erection and equipment of the necessary buildings and $175,000 annually for the maintenance and operation of the experiment station.

The cooperative research program at the Pennsylvania State College, which has been financially supported for 4 years by the Commonwealth of Pennsylvania and the anthracite industry, was extended for a period ending May 31, 1945.

Research undertaken by Anthracite Industries, Inc., is discussed elsewhere in this chapter under the subheading Anthracite Industries, Inc.

Competitive fuels in the United States and principal markets.—The principal anthracite markets are the New England States, New York, New Jersey, Pennsylvania, Maryland, Delaware, and District of Columbia. Data on the consumption of all fuels in these markets are not available; however, the apparent consumption of anthracite, coke, briquets, and heating and range oils, in terms of anthracite, increased 2.7 percent in 1942 over 1941. Virtually all of the increase in consumption is attributable to increased shipments of anthracite to this area. In 1942 anthracite supplied 59.2 percent of the total equivalent fuels consumed in these States. In addition to the legitimate anthracite shipped, large quantities of illicit or "bootleg" coal are moved by truck to these States. The demand for metallurgical coke was largely responsible for the decline in domestic consumption of 28.7 percent in 1943 compared with 1940.

Details on consumption of competitive fuels are shown in table 3.

TABLE 3.—*Apparent consumption of anthracite and selected competitive fuels in the principal anthracite markets, 1940–43*

[1] Pennsylvania Department of Mines; illicit coal not included.
[2] An important but undetermined part of anthracite shown as shipped to New Jersey is reshipped New York City.
[3] Data not yet available.
[4] U. S. Department of Commerce.
[5] Less than 1,000 tons.
[6] Converted to coal equivalent upon basis of 4 barrels of fuel oil equaling 1 ton of coal.
[7] Excludes bituminous coal.

In general, the supplies of fuel commonly used for space heating in the United States increased in 1943 over 1942. Although the consumption of anthracite was not much greater than in 1942, it would have increased sharply had it not been for the curtailment of production caused by strikes and labor disturbances in the anthracite fields. Although the consumption of oil declined in some areas, an increase was shown for the United States as a whole. Details on supplies of various fuels are given in table 4.

TABLE 4.—*Total supplies of fuels commonly used for space-heating purposes in the United States, 1924 and 1940–43*

[Wherever available, figures represent quantity actually consumed for domestic heating or for space heating offices, apartments, hotels, schools, hospitals, etc. Where such figures are not available but where the fuel is known to be used chiefly for domestic or space-heating purposes, total production (or imports) is shown to indicate trend of growth]

[1] A considerable part of the smaller steam sizes is used by industries, railroads, and public utilities.
[2] Production plus imports less exports.
[3] Partly estimated.
[4] Data not available.
[5] An estimated one-half is used for domestic purposes.
[6] Exact data not available; estimated between 55 and 77 million tons a year, including lignite. Anthracite and semianthracite outside Pennsylvania, shown separately.
[7] Estimated.
[8] Includes all grades of fuel oil used for heating buildings.
[9] Includes gas used for heating offices, hotels, apartments, schools, hospitals, and stores and other large buildings, as well as houses.
[10] American Gas Association.
[11] Data not yet available.

Transportation and distribution of anthracite to principal markets.—The Bureau of Mines, in cooperation with Solid Fuels Administration for War, canvassed shippers of Pennsylvania anthracite for detailed data showing the distribution of anthracite to ultimate destinations for the coal year 1942–43. The shipments were reported by method of movement (rail, truck, tidewater, and lake) and by kinds of consumers (retail dealers, railroads, utilities, United States Government, States, municipalities, and others). To a great extent the Solid Fuels Administration for War bases its procedure for distributing and allocating anthracite upon these statistics compiled by the Bureau of Mines.

Table 5 gives shipments of anthracite by States of destination, as reported by the producers and wholesalers. It will be noted from

TABLE 5.—*Shipments of Pennsylvania anthracite, Apr. 1, 1942, to Mar. 31, 1943, by States of destination, in net tons* [1]

[1] As reported by producers and wholesalers on Solid Fuels Administration for War form SFA-6.
[2] Less than 0.01 percent.
[3] Includes California, Idaho, Nevada, Utah, Washington, and Wyoming.
[4] Coal sold to over-the-road truckers for which destinations were not reported.

this table that 86.16 percent of the total anthracite shipments was destined to the New England and Middle Atlantic States and that 1.37 percent (810,000 tons) was destined to unknown States. All of this coal shipped to unknown States moved by truck from the mines, and it is safe to assume that virtually all of it was destined to New York, New Jersey, and Pennsylvania. Thus shipments of anthracite to the New England and Middle Atlantic States approximated 88 percent of the total anthracite shipped to destinations in the United States and Canada during the coal year 1942–43.

According to data compiled from records of the Pennsylvania Department of Mines, shipments of anthracite, by truck, from mines to markets declined from 7,955,738 net tons in 1942 to 7,877,860 net tons in 1943. In 1942 and 1943 the trucked coal represented 15 and 14.7 percent, respectively, of the total anthracite shipments to destinations in the United States. The State figures represent legitimate coal and some anthracite from illicit or "bootleg" mines, nearly all of which is trucked to market; river coal dredged from the streams draining the anthracite region is not included. In 1943 Pennsylvania received 76 percent of the total trucked shipments, and New Jersey and New York followed with 11 and 9 percent, respectively, whereas in 1942 these three States received 71, 15, and 11 percent, respectively. Anthracite rail shipments by States of destinations for 1941–43 are shown in table 6 and truck movement by months for 1942–43 is given in table 7.

[1] Compiled from reports of Pennsylvania Department of Mines.

According to data compiled from records of the Commonwealth of Massachusetts, Division on the Necessaries of Life, and the Anthracite Emergency Tidewater Bureau, rail receipts of Pennsylvania anthracite in New England in 1943 declined 1.5 percent from 1942; tidewater receipts, 6.8 percent. Table 8 gives details of anthracite movement to New England. Loadings at Lake Erie ports increased 14.9 percent in 1943 over 1942; receipts at upper Lake docks, 6.3 percent.

[1] Commonwealth of Massachusetts, Division on the Necessaries of Life.
[2] U. S. Department of Commerce.
[3] Total receipts by rail and by tide less imports.

Figure 1 presents graphically shipments of anthracite from the Lehigh, Schuylkill, and Wyoming regions, 1850 to 1943, inclusive.

Consumption.—Consumption of anthracite in the United States in 1943, including colliery fuel, amounted to 57,100,000 net tons, an increase of 600,000 tons over the calculated consumption in 1942. These figures consider imports, exports, and changes in producers' stocks of anthracite but do not allow for changes in stocks held by retail dealers and small consumers, as data on changes of stocks in these groups were insufficient. Since there was a shortage of anthracite in 1943, stocks held by retail dealers no doubt declined to a very low level, and actual consumption probably was much higher than the figure mentioned. Electric-power utilities and class I railroads consumed 4,465,578 tons of anthracite in 1943 compared with 4,009,095 tons in 1942.

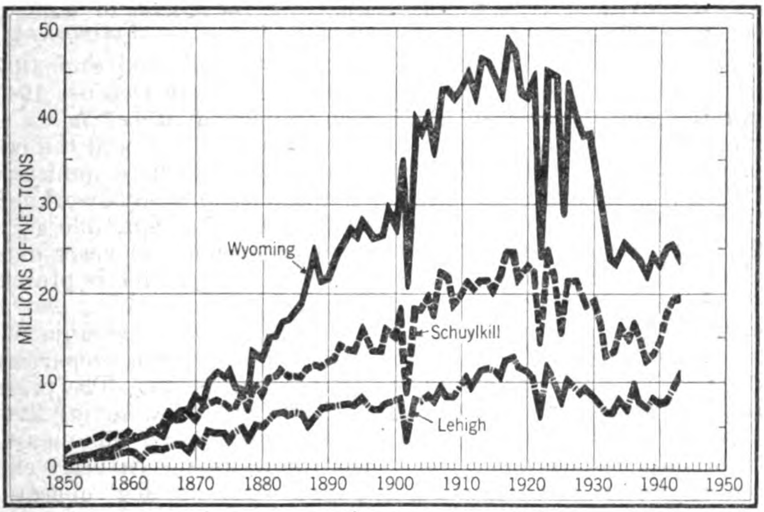

FIGURE 1.—Anthracite shipped from the Lehigh, Schuylkill, and Wyoming regions, 1850–1943.

Changes in stocks.—The great demand for anthracite in 1943, especially domestic sizes and Buckwheat No. 1, caused producers to draw heavily on their stocks, resulting in a decline of 58.8 percent from 1942. Virtually all of the coal in storage at the close of 1943 was Buckwheat No. 2 or smaller.

Stocks held by public utilities in 1943 increased 14.3 percent over 1942; however, stocks held by railroads (class I only) and upper Lake docks declined 26.2 and 29.2 percent, respectively.

Days' supply of anthracite held by retail dealers declined from 21 days in January 1943 to 12 days in December 1943.

Illicit coal.—The efforts of the Anthracite Committee to abolish "bootleg" mining of anthracite are evidently successful, as the output of anthracite by the illicit mining industry declined from 3,931,000 net tons in 1942 to 1,912,000 tons in 1943. The output in 1941 was estimated at 5,000,000 net tons.

The committee announced that, as of November 30, 1943, the industry would cease to purchase "bootleg" coal for preparation. The committee, in accordance with the provisions of Act of Assembly No. 125, approved July 7, 1941, adopted a resolution on October 15 which explained the situation, in part, as follows:

> Seventy-five percent of those formerly engaged in bootlegging have accepted employment in legitimate industry. The insistence of a minority in continuing to work as bootleggers and their refusal to accept employment in legitimate industry, of which there is ample evidence, is harmful to the war effort of the Nation. Their course lessens the tax revenues and the production of the Nation.
>
> The situations created by bootlegging are not limited to the money losses sustained by landowners whose coal has been unlawfully taken, or to the harm done to the Anthracite Industry and to the public by the marketing of an inferior fuel, or to the coal which has been irretrievably lost through the unsound mining practices of bootleggers. The greatest harm lies in the hazards to future deep mining, which bootleggers have created, and in the destruction of taxable wealth.

A survey by the committee in March 1941 indicated that 10,762 men were working 3,006 "bootleg" holes, whereas in October 1943 a comparable survey revealed 2,725 men employed in 791 holes. In March 1944 the number of holes had decreased to 652, and the number of men employed totaled 2,220. A survey by the committee in May 1942 revealed that 45 percent of the men and boys working in "bootleg" holes were less than 30 years old. A comparable survey in March 1944 indicated that the percentage under 30 years of age had declined to 28 percent. A large part of this decline is probably due to the younger men entering the armed forces.

Early in 1943 a bill was introduced before the Pennsylvania State Legislature requiring inspections, by the Pennsylvania Department of Mines, of all openings employing two or more men. The present law requires periodic inspection only of those mines employing five or more men. The legislature adjourned without passing this measure; had it become law, it would have been the means of virtually eliminating the illicit mining industry, as most of the "bootleg" operations would have experienced difficulty in meeting the safety standards maintained by the legitimate industry.

Trend of employment.—The number of employees in the anthracite industry continued to decrease in 1943. At the close of the year a shortage of several thousand men below the number necessary to meet production requirements existed within the industry. Employment dropped from an average of 88,054 men in 1941 to 82,121 men in 1942 and 79,153 men in 1943. The greater part of the decline occurred among underground miners and their laborers. The induction of men into the armed forces and the loss of others to nearby war industries were largely responsible for the decrease. These employment figures do not include men working in "bootleg" holes. Data on employment are given in tables 22 and 23.

Sales realization.—The average realization on breaker shipments increased from $4.79 a net ton in 1942 to $5.38 in 1943—an increase of 12.3 percent. The average value per net ton of the total anthracite production in 1943 was $5.06 compared with $4.50 in 1942.

Trend in prices.—Anthracite f. o. b. mine prices were increased substantially in 1943 because of added production costs. Effective January 9, 1943, the Office of Price Administration authorized an increase in maximum prices of anthracite of approximately 50 cents a net ton. The price increase reflected higher production costs incident to extension of the work week from 5 to 6 days, and the payment of time and a half and rate and a half for the sixth consecutive day worked in any 1 week. The new prices as of January 9, 1943, were $7.30 per net ton f. o. b. mine for Broken, Egg, Stove, and Chestnut sizes; $5.75 for Pea; and $4.20, $3.35, and $2.50 for Buckwheat No. 1, Rice, and Barley sizes, respectively.

When the miners failed to report for work on November 1, 1943, the Federal Government took possession of the anthracite mines, and the Secretary of the Interior in his official capacity as Coal Mines Administrator reached an agreement with the United Mine Workers on November 3. To compensate the anthracite producers for increased labor costs allowable under the Little Steel formula and the agreement of November 3, the Office of Price Administration authorized, effective November 24, an average increase in anthracite f. o. b. mine prices of about 62 cents a net ton. The new prices were as follows: Broken, Egg, Stove, and Chestnut sizes, $8.00 a net ton; Pea, $6.45; Buckwheat No. 1, $4.80; Rice, $3.85; Barley, $2.85; and smaller than Barley size, $2.15 a ton. On June 1, 1944, the new f. o. b. mine prices were reduced an average of 14 cents a ton leaving an increase of 48 cents a net ton. The larger increases up to June 1, 1944, are to permit the producers to recover the amount of labor costs made retroactive to May 1, 1943, by the War Labor Board.

On January 29, 1944, the Solid Fuels Administrator for War directed the Federal operating managers of the anthracite mines to give the miners an opportunity to work four Sundays in February to increase the output of anthracite. To compensate the anthracite producers for added costs of production for the month of February by reason of four consecutive 7-day weeks the Office of Price Administration authorized an increase of 45 cents a net ton in the f. o. b. mine prices of anthracite for all coal loaded at the preparation plants for shipment during the month of February. Thus the maximum February prices were: Broken, Egg, Stove, and Chestnut, $8.45; Pea, $6.90; Buckwheat No. 1, $5.25; Rice, $4.30; and Barley, $3.30 a net ton, respectively. On March 1, 1944, the mine prices reverted to those in effect in January 1944.

Retail prices of anthracite, bituminous coal, coke, and heating oils in selected cities, by months, in 1943 are shown in table 9. These prices were compiled from reports of the Bureau of Labor Statistics United States Department of Labor.

[1] Compiled from reports of Bureau of Labor Statistics, U. S. Department of Labor. Prices are as of the 15th of each month. Data are preliminary.

[2] Not available.

[3] Insufficient data.

[4] Includes 2-percent sales tax.

[5] Includes 1-percent sales tax.

[6] Prices of coal per ton of 2,240 pounds.

Imports and exports.—In 1943 almost all exports of anthracite were destined to Canada, where continued restrictions on the use of heating oils and gas for domestic purposes and a shortage of coke created a great demand for Pennsylvania anthracite. In 1943 exports of anthracite declined 6.8 percent from 1942, whereas imports increased 18.5 percent. For details on exports and imports see tables 30 and 31.

Mechanical stokers and oil burners.—According to the Bureau of the Census, United States Department of Commerce, factory sales of class 1 mechanical stokers (capacity under 61 pounds of coal per hour) declined from 17,110 in 1941 to 11,562 in 1942 and in 1943 totaled only 472 units; sales of class 2 stokers (capacity, 61 to 100 pounds of coal per hour) totaled 599 units in 1941, declined to 356 in 1942, and then increased to 2,043 units in 1943. Shipments of oil burners for central heating plants and industrial use totaled 303,869 units in 1941, declined to 131,031 units in 1942, and fell in 1943 to 72,563 units. Government restrictions on the manufacture and installation of stokers and oil burners were largely responsible for the general decline in the sales of this equipment in 1943.

POST-WAR OUTLOOK

The position of anthracite in relation to other competitive fuels in the post-war period will depend largely on steps taken during the war and immediately after to develop low-cost, automatic burning equipment; to find new uses for anthracite; and to establish new production methods that will reduce mining costs. The establishment and operation of a research laboratory in the anthracite region as provided by act of Congress (S. 357) and the expanded research program of Anthracite Industries, Inc., will be of considerable value to the industry in the post-war period. Research provisions contained in S. 357 are discussed elsewhere in this chapter under the subheading Research; activities of Anthracite Industries, Inc., are covered in detail under subheading Anthracite Industries, Inc.

SOURCES AND ACKNOWLEDGMENTS

Final statistics of the Pennsylvania anthracite-mining industry are prepared from an annual canvass, by mail, of the producers and shippers of anthracite. About 95 percent of the tonnage is reported direct, and the remaining 5 percent is collected by personal visits or from reliable collateral evidence. The data on individual operations are furnished voluntarily by the producers and treated confidentially, as is customary in the statistical services of the Bureau of Mines.

In assembling available detailed information, free use has been made of the pertinent figures prepared by the Anthracite Institute, the Anthracite Committee, the Association of American Railroads, and the Pennsylvania Department of Mines; to all of these thanks are extended for their cordial and continued cooperation. Thanks are also due especially to the producers for reporting so promptly and so fully upon their 1943 operations.

PRODUCTION

The production statistics of the Pennsylvania anthracite industry contained in this chapter include coal from five sources—deep mines, strip pits, culm banks, "bootleg" mines, and rivers. A small quantity of semianthracite produced in Sullivan County (97,720 net tons in 1943) is also included for historical comparison. The total production from these sources in 1943 was 60,644,000 net tons, a gain of 316,000 net tons over the 1942 output of 60,328,000 net tons.

See tables 10 to 18 for production and shipments by regions, fields, and counties.

Before 1941 "bootleg" coal was not included in the production statistics of the Pennsylvania anthracite industry by the Bureau of Mines; however, in 1941 the Anthracite Committee inaugurated a plan whereby legitimate operators purchased lawfully the run-of-mine output of "bootleg" holes for preparation at their plants and shipment to market. In 1942 these shipments totaled 2,616,839 net tons; in 1943 the purchases were 1,265,617 tons. It would be impossible to segregate this purchased "bootleg" coal from the output of the legitimate industry. For this reason, it is included in the various production tables in the Minerals Yearbook chapters on Pennsylvania anthracite for 1941–43. The production statistics for those years, therefore, are not exactly comparable with previous years. No attempt has been made to include in the statistics "bootleg" coal other than that purchased by legitimate operators. To compute the output per man per day for the anthracite industry in 1941–43 it was necessary to deduct the "bootleg" purchases from the total tonnage shipped by the legitimate industry since adequate data on man-hours required to produce the "bootleg" tonnage are not available. Details of this procedure are discussed in this chapter under Labor Statistics.

Weeks and months.—Tables 10 and 11 summarize the statistics of weekly and monthly production of anthracite. Statistics of current output are estimated from records of car loadings and from tonnage

[1] Production is estimated from weekly carloadings as reported by the Association of American Railroads and includes mine fuel, coal sold locally, and dredge coal. Monthly statistics from 1905 to 1925 will be found in Mineral Resources, 1925, pt. II, pp. 427–428, and from 1925 to 1930 in Mineral Resources, 1930, pt. II, p. 741.

[2] Includes some "bootleg" coal purchased by legitimate operators and prepared at their breakers.

Reconciliation of fresh-mined, culm-bank, and breaker product.—Anthracite is now produced from three sources—mines, culm banks, and rivers that drain the anthracite region. As all three sources contribute to the country's supply, it is important to consider them all to ascertain the total production. No difficulty is experienced in separating the figures of production by dredges, as this is a distinct industry. It is difficult, however, to make a sharp differentiation between fresh-mined and culm-bank coal, continuity of which may be maintained in the statistical history of the industry.

As the best solution of this problem, the individual breaker, washery, or dredge is taken as the unit in compiling the statistics, and the producing companies are asked to supply separate statements for each. These are totaled to form the primary tables of this report to show the total quantity of breaker product, washery product, and dredge product, with related figures of value and number of employees.

The figures for breaker and washery product, however, are not exactly equivalent to the fresh-mined and culm-bank coal because of the practice sometimes adopted of putting culm-bank coal through a breaker, either directly from the bank or after preliminary treatment in a washery. The tonnage of culm-bank coal prepared at the breakers is broken down by fields and shown in table 17.

Small mines and intercompany sales.—In recent years conditions have favored the development of numerous small mines operating on lease or subcontract and producing run-of-mine coal, which is sold to larger companies for preparation at a breaker. (This refers to legitimate mines only and does not concern illicit or "bootleg" mines.) At the same time, an increasing transfer of coal from one operation to another has developed, and some of the companies have built central breakers to which coal from numerous mines is shipped by rail or truck for preparation. These developments have increased the complexity of the task of collecting and compiling statistics of the industry. Great care has been exercised, however, to avoid double counting of tonnages produced by one operator and prepared for market by another, and the figures herein represent the net quantity of merchantable coal plus the fuel used by the collieries themselves. The employees of operators producing run-of-mine coal only have been included in the employment statistics, as they have received wages from the industry and have contributed to the final product.

Regions, fields, and counties.—The anthracite fields are divided into three trade regions—Lehigh, Schuylkill, and Wyoming. This classification is generally used by the trade, and it is also followed in the district organization of the United Mine Workers of America, in which district 1 corresponds to the Wyoming region, district 7 to the Lehigh region, and district 9 to the Schuylkill region. Geologically the anthracite area is classified by fields—the Northern, Eastern Middle, Western Middle, and Southern. This classification is used in technical operating studies because it follows more closely the geologic conditions that largely influence the methods and cost of mining. The Northern field is the same as the Wyoming region; the Eastern Middle field and that part of the Southern field lying east of Tamaqua (known as the Panther Creek Valley) make up the Lehigh region; the Schuylkill region comprises that part of the Southern field lying west of Tamaqua and the Western Middle field. For historical comparison, the tonnage of the small Bernice Basin is often included with the statistics of the Northern field, although the coal is classified officially as semianthracite. The total area of the four fields is about 484 square miles—the Northern covers 176 square miles, the Eastern Middle 33, the Western Middle 94, and the Southern 181.

Based upon minable reserves the Southern field is first, followed by the Western Middle, Northern, and Eastern Middle.

Tables 12 to 19 present production data by regions, fields, and counties.

---

[1] Value given is value at which coal left possession of producing company; does not include margins of separately incorporated sales companies.

[2] For purposes of historical comparison and statistical convenience, the mines of Sullivan County are grouped with the Pennsylvania anthracite region, although the product is classified as semianthracite according to the American Society for Testing Materials Tentative Standard.

[3] A small quantity of washery coal included with breaker.

TABLE 13.—*Pennsylvania anthracite produced, 1939–43, by fields, in net tons*

[The figures of breaker product include a certain quantity of culm-bank coal, which amounted to 5,027,899 tons in 1943. Data for 1913–25 will be found in Mineral Resources, 1925, pt. II, p. 517, and for 1919–30 in Mineral Resources 1930, pt. II, p. 747]

[1] Small quantity of washery coal included with breaker.

Culm-bank coal.—The culm banks in the anthracite region have been a source of coal for many years. In the early days of anthracite mining, the smaller sizes of anthracite, especially Pea and under, were not used as they are today, and these sizes and larger pieces of refuse containing much good coal were piled in large banks throughout the region. In recent years, with the increased demand for the smaller sizes and more efficient preparation methods, the product of these banks is run through the washery or breaker, and a prepared coal is obtained.

In 1942 this source supplied 4,735,064 net tons of coal. Prepared coal from culm banks in 1943 amounted to 7,583,698 tons. Tables 15 to 17 give a detailed break-down of culm-bank product by regions and fields.

TABLE 17.—*Culm-bank coal put through breakers, 1939–43, by fields, in net tons*

Year	Northern	Eastern Middle	Western Middle	Southern	Total
1939	70,000	17,000	204,000	295,000	586,000
1940	13,000	[1] 139,000	250,000	362,000	764,000
1941	113,000	57,000	519,000	387,000	1,076,000
1942	291,000	420,000	1,413,000	524,000	2,648,000
1943	[1 2] 630,000	1,088,000	2,102,000	1,208,000	[1] 5,028,000

[1] Includes some washery coal.

[2] A small quantity of culm-bank coal was put through breakers in Sullivan County.

[1] Figures of shipments from breakers include some culm bank coal handled in the breakers.

[2] Quantity of Lump included is insignificant.

[3] A small amount of Pea included in Buckwheat No. 1.

[4] A small amount of Other included in Buckwheat No. 4.

Interregional variation in sizes.—The relative yield of domestic and steam sizes of anthracite in the three regions is greatly affected by geologic conditions, mining methods, and the quantity of culm-bank coal recovered.

In 1943, the breaker output of the Wyoming region consisted of 72 percent domestic and 28 percent steam sizes; the Lehigh region, 57.9 percent domestic and 42.1 percent steam sizes; the Schuylkill region, 54 percent domestic and 46 percent steam sizes. Table 18 shows shipments of anthracite by regions and sizes. Table 19 shows the percentages, by regions, of various sizes in relation to total breaker product.

TABLE 19.—*Sizes of Pennsylvania anthracite shipped from breakers, 1941–43, by regions, in percent of total*

AVERAGE VALUE AND SALES REALIZATION

The valuation figures in this study represent value at the breaker or washery reported by the operating companies. The company is requested to "estimate value of the product not sold" and to "exclude selling expenses" in making its report.

From this it will be seen that when a producing concern sells its output to a separately organized sales company the value reported will exclude the margin of the sales company and may therefore be somewhat less than the circular price at which the coal is placed on the general market. This fact should be borne in mind in considering the variations in value among different regions, shown in the tables, for the same sizes of coal.

The average sales realization per net ton on breaker shipments was $5.38 in 1943 compared with $4.79 in 1942—a 12.3-percent increase (see table 20).

With the inclusion of local sales, colliery fuel, washery coal, and dredge coal the average value per net ton of the total 1943 production is $5.06 compared with $4.50 in 1942 (see table 21).

[1] Value given for shipments is value at which coal left possession of producing company and does not include margins of separately incorporated sales companies.

LABOR STATISTICS

A labor shortage of several thousand men characterized the Pennsylvania anthracite industry in 1943, when the average number of men employed was 79,153—a decrease of 2,968 from the total of 82,121 men employed in 1942. Many men formerly employed in the anthracite mines entered the armed forces, and others obtained employment in nearby war industries.

The employment statistics in this chapter do not include workers in "bootleg" or illicit coal mining, which is conducted in the Southern and Western Middle fields of the Pennsylvania anthracite regions. According to the Anthracite Committee, 7,554 men were working 2,029 "bootleg" holes in May 1942, and in March 1944 a comparable survey revealed 2,220 men employed in 652 holes. Although these workers are not included in the employment data, the coal produced by some of them was purchased by the legitimate industry for preparation and shipment to market, and coal so purchased is included in the production tables of this chapter. Complete employment data for the "bootleg" holes from which this coal was produced are not available. In calculating the output per man per day, therefore, the tons of "bootleg" coal purchased by the legitimate industry were deducted from the total tonnage reported by the operators, and the resulting legitimate production was then used to calculate the output per man per day. It is true that part of the time of the men employed at the preparation plants of the legitimate companies was used to prepare this purchased coal for market; however, on a per-ton basis this time is insignificant, and its omission will not detract materially from the validity of the result obtained.

See tables 22 and 23 for details on labor statistics.

Sullivan	97	151			

[1] None in Lebanon in 1942.

[2] Counties producing dredge coal only.

[3] None in Perry and York in 1943.

EQUIPMENT AND METHODS OF MINING

Mechanical loading.—The percentage of total deep-mined production of anthracite loaded mechanically continued to increase. In 1943 the 14,746,000 tons so loaded comprised 34.5 percent of the total underground output compared with 32.6 percent (14,741,000 tons) in 1942 and 30.6 percent (13,442,000 tons) in 1941 (see tables 24 to 26).

Mechanical loading has increased more rapidly in the Northern field than in the other three anthracite-producing districts. The reason for this is that the coal measures in the Northern field are more

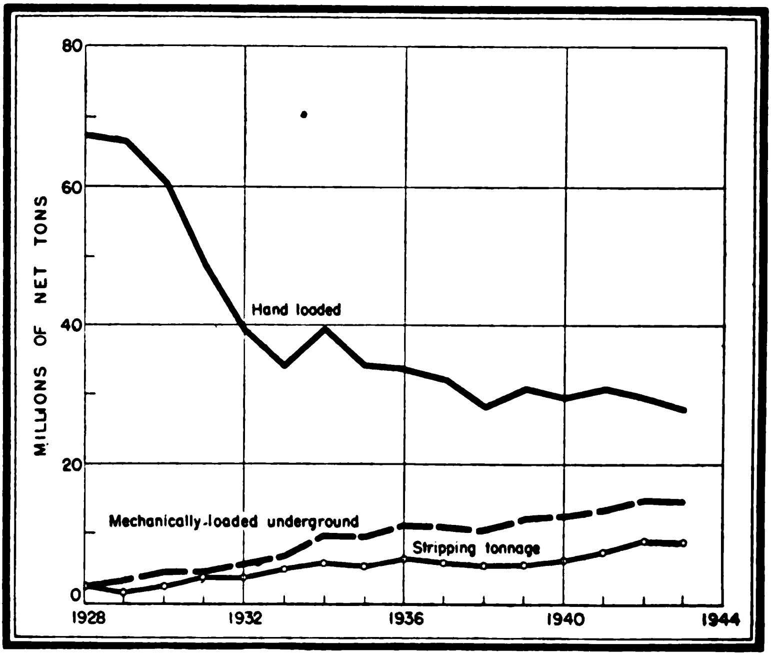

FIGURE 2.—Relative growth of mechanical loading, hand loading, and stripping of Pennsylvania anthracite, 1928–43.

adaptable to current mechanical coal-loading methods than those in the Lehigh and Schuylkill regions. In 1943 the tonnage loaded mechanically in the Northern field was more than four times that in the Western Middle, Eastern Middle, and Southern fields combined. Figure 2 illustrates the relative growth of underground mechanical and hand loading and of stripping, 1928–43.

TABLE 24.—*Relative growth of mechanical loading, hand loading, and stripping in Pennsylvania anthracite mines, 1939–43*

[1] Includes duckbills and other self-loading conveyors, which handle only a small part of the total.
[2] Includes mobile loaders

Strip-pit operations.—Strip-pit operations to recover anthracite are conducted extensively throughout the region. The mountains surrounding the anthracite fields are steep and rugged, and in the Lehigh and Schuylkill regions (which are more adaptable to large-scale strip-pit mining than the Wyoming region) the coal pitches sharply from the sides to the valleys below; in the Wyoming region the coal beds are comparatively flat. Strip mining of anthracite was begun in the early 1800's when the overburden was removed by hand or by horse-drawn scrapers. The output by this method of mining in the early years was small, and only the coal that was readily accessible was recovered.

The Federal Geological Survey began to collect statistics on the stripping of anthracite in 1915, when the output by this method of mining was 1,122,000 net tons (1.3 percent of the fresh-mined production). In 1942, according to reports received by the Bureau of Mines from producers, the output from strip pits totaled 9,071,000 tons (16.7 percent of the fresh-mined coal), and in 1943 this method of mining supplied 8,989,387 tons (17.4 percent of the total fresh-mined production).

Although the Wyoming region has been the chief producer of anthracite for more than 60 years, the Lehigh and Schuylkill regions surpass it in tonnage recovered from strip pits. In 1920 when strip-pit coal was 2.5 percent of the industry's fresh-mined output, only 0.6 percent of the Wyoming region's fresh-mined coal came from strip pits, whereas comparable figures for Lehigh and Schuylkill regions were 9.4 and 2.6 percent, respectively. In 1943 when the production from strip pits increased to 17.4 percent of the industry's fresh-mined tonnage, 5 percent of the fresh-mined coal in the Wyoming region came from strip pits, but in the Lehigh and Schuylkill regions strip-pit mining supplied 23.3 and 35.3 percent, respectively, of the fresh-mined total of these regions. The high proportionate tonnage obtained in the Lehigh and Schuylkill regions by stripping operations is due partly to the relative ease of mining thick bed outcrops and partly to the necessity for reducing the over-all costs of production to meet price competition from other fuels. In the Wyoming region beds are thinner and generally flat, thus limiting the quantity of coal uncovered for a given area. Table 27 gives pertinent statistics for certain years during the period 1915–1943. Figure 3 illustrates

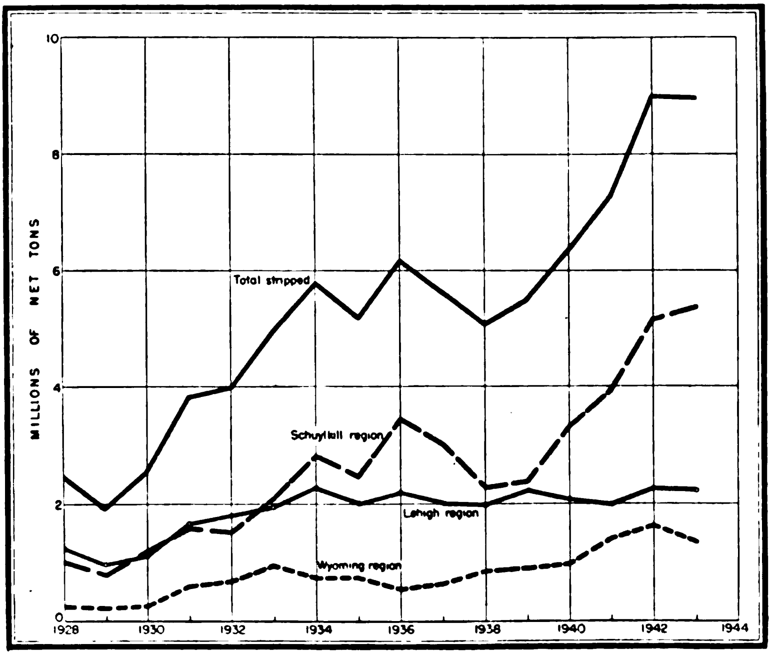

FIGURE 3.—Pennsylvania anthracite mined from strip pits, by regions, 1928–43.

graphically the production of anthracite from strip pits, by regions, 1928–43.

Cutting machines.—The quantity of anthracite cut by machines in 1943 was 1,624,883 net tons compared with 2,285,640 tons in 1942, a 28.9-percent decrease. Details are shown in table 28.

Dredge coal.—Dredging anthracite from the stream beds is an important industry to many operators along the banks of the rivers and creeks that drain the anthracite regions. River coal was first dredged in the 1890's, but the earliest production reports received by the Geological Survey were for 1909. From 1909 to 1942, inclusive, dredge operators reported—to the Geological Survey and subsequently to the Bureau of Mines—the recovery of 20,427,129 net tons, and although this is only a small fraction of the total output of anthracite it is important from the standpoint of conservation of natural resources. The industry reached a peak in 1941, when 1,518,000 net tons of anthracite with a value of $1,840,000 were taken from the river and creek beds. In 1943 this source supplied 1,334,737 net tons of anthracite valued at $1,972,777. (See table 29.)

TABLE 29.—*Pennsylvania anthracite produced by dredges in 1943, by rivers*

River (including tributaries)	Net tons	Value	
		Total	Average
Lehigh	37,452	$60,037	$1.60
Schuylkill	342,815	440,055	1.28
Susquehanna	954,470	1,472,685	1.54
	1,334,737	1,972,777	1.48

FOREIGN TRADE [1]

Anthracite exported from the United States in 1943 totaled 4,138,680 net tons compared with 4,438,588 tons in 1942. Virtually all the exported coal was shipped to Canada, where shortages of heating gas and coke created a strong demand for anthracite. Details of imports and exports are shown in tables 30 and 31.

Canadian market.—Coal and lignite production in Canada in 1943 decreased 5.7 percent from 1942, whereas coke production increased 8.4 percent. Imports of anthracite in 1943 decreased 7.2 percent from 1942, but imports of bituminous coal increased 17.2 percent. Coal available for consumption in 1943 was 4.3 percent more than in 1942 and coke, 12.5 percent.

See table 32 for coal and coke statistics in Canada.

SUMMARY

In 1943, the second full year of United States participation in World War II, the coke industry contributed coke and coke byproducts—all indispensable for war—in quantities never equaled before. The combined production of byproduct and beehive coke was 71,676,063 tons—63,742,676 tons (89 percent) of byproduct and 7,933,387 tons (11 percent) of beehive—an increase of 1,107,119 tons (2 percent) over the previous peak output in 1942. This increase resulted entirely from the record output of byproduct coke, which increased 1,447,767 tons (2 percent), a gain that more than offset the decline of 340,648 tons (4 percent) in beehive-coke output. The record was the more remarkable as it was accomplished in the face of mine shut-downs and the unavoidable drain of manpower into the armed forces. The effects of mine stoppages, which forced many byproduct-oven operators to slow their coking operations to conserve available supplies of coking coal, are clearly illustrated in figure 1; however, this loss in production was offset in part by the completion of 953 new byproduct ovens during the year, which added 5,220,610 tons to the annual coke-producing capacity of the industry, so that by December the average daily rate of production was 3 percent higher than in January. In the beehive industry many operators were handicapped by the lack of coking coal, in addition to production losses that resulted from mine stoppages, labor shortages, and transportation difficulties, all of which explained the decline in beehive-coke production from 1942.

A survey of employment in the coke industry in 1943 showed 21,632 men employed at byproduct plants and 4,133 at beehive plants; the average output per man per year was 2,947 tons of byproduct and 1,920 tons of beehive coke. In 1918, the year of World War I, the average output per man per year was 1,630 tons for byproduct and 1,854 tons for beehive coke. The increased output of byproduct coke per man per year since 1918 resulted from progress in coke-oven design and mechanical equipment.

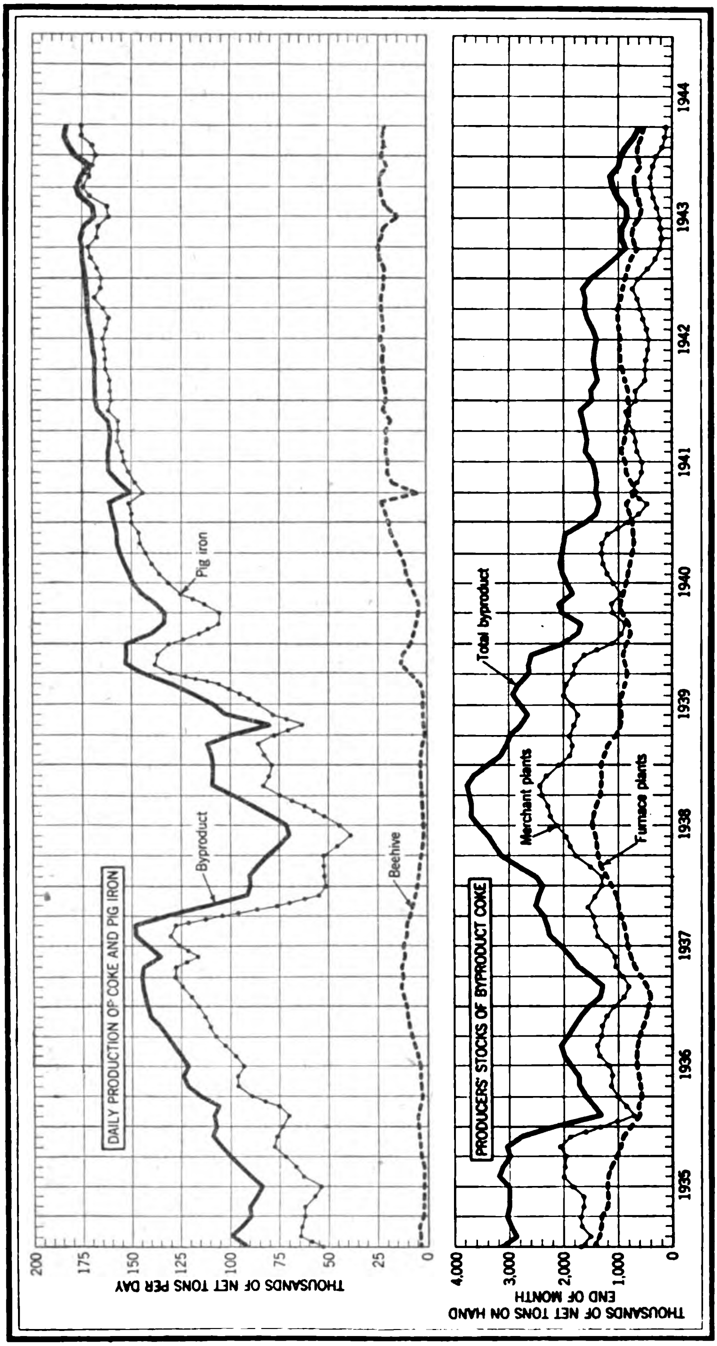

FIGURE 1.—Average daily production of beehive and byproduct coke and pig iron and producers' stocks of byproduct coke, 1935–43, by months.

The average value per ton of coal charged into byproduct and beehive ovens, which has been climbing since 1940, increased 10 percent over the 1942 figure; the average cost of byproduct coal in 1943 increased $0.37, and for beehive ovens the cost rose $0.52 per ton.

The enormous requirements of blast-furnace coke by an expanded iron and steel industry resulted in a movement of nearly 80 percent of byproduct output and 86 percent of beehive to furnaces. According to producers' reports, the quantity of coke used by producers, sold to financially affiliated corporations, or sold to other companies for blast furnace use totaled 57,690,160 tons—50,885,639 tons of byproduct (88 percent) and 6,804,521 tons of beehive (12 percent)—an increase of 4 percent over the quantity so used in 1952. The disposal of coke for other industrial purposes (for foundry use, for the manufacture of producer and water gas, for nonferrous smelting, and for miscellaneous industrial uses) reached a new high in 1943 and totaled 9,606,773 tons compared with 9,190,418 tons so used in 1942. The quantity of coke sold for domestic heating, which has dropped steadily since 1940 because of diversion to the metallurgical industries, decreased 19 percent from the preceding year.

Coke prices increased in general in 1943 because of increases in coal and manufacturing costs. The average realization per ton of furnace coke sold gained $0.73 and was $6.89 in 1943; in the same period, foundry coke advanced $0.10 to $9.85; the unit value of coke sold for the manufacture of water gas increased $0.27 and averaged $7.80; coke sold for other industrial uses climbed $0.23 per ton to $7.11; domestic coke prices followed the sharp upward trends of industrial coke and averaged $8.17 compared with $7.84 in 1942. The price of screenings or breeze increased markedly over 1942 and was $2.95 per ton.

Stocks of coke declined sharply in 1943 and dropped to 862,100 tons on January 1, 1944, the lowest level since January 1, 1926. Furnace-coke stocks at producers' plants decreased 31 percent, and domestic coke stocks declined 56 percent from those at the end of 1942.

Coke exported in 1943 amounted to 994,607 tons—an increase of 18 percent over 1942. Imports of coke totaled 98,127 tons and were 10 percent less than in 1942.

The increased activity in the byproduct industry during 1943, which saw all furnace plants operating toward maximum output of coke, had a marked effect on the production of the four principal byproducts of the coking process. The output of gas and crude light oil increased in 1943 compared with 1942, whereas the production of crude tar and ammonia decreased. The output of coke-oven gas was 15,574,881 M cubic feet higher than in 1942 and totaled 960,454,518 M cubic feet, and crude light oil output gained 4,486,213 gallons to 250,511,095 gallons; but crude tar output dropped 2,008,651 gallons to 738,166,968 gallons, and ammonium sulfate or equivalent declined 9,639,714 pounds to 1,795,386,007 pounds.

The total value of all coke, breeze, and tar produced and of other byproducts sold in 1943 was $686,428,948, a new record, representing an increase of $57,020,526 (9 percent) over 1942.

GOVERNMENT CONTROL MEASURES

In previous Coke and Byproducts chapters, various control measures relating to coke and coke byproducts have been summarized. This review carries the record forward to January 1, 1944.

Byproduct coke.—Maximum prices for byproduct coke from January 1, 1943, to December 6, 1943, were governed by the Office of Price Administration Revised Price Schedule 29 and Maximum Price Regulation 121, with subsequent amendments. To bring these together in one form the Office of Price Administration issued Maximum Price Regulation 29 on December 6, 1943, effective the same day. This regulation covered ceiling prices on all byproduct and retort-gas coke produced in the United States. Amendment 1 to Maximum Price Regulation 29, issued December 20, 1943, effective the same day, increased the maximum prices of byproduct coke produced in the South and Midwest by $0.30 per ton.

In order that byproduct and beehive coke could be placed under allocation if it became necessary, the War Production Board issued General Preference Order M–292 on March 12, 1943. This regulation made it mandatory for all byproduct- and beehive-coke producers to file monthly report forms with the Bureau of Mines—Form BY for byproduct and Form BE for beehive.

Authority covering the distribution of domestic coke was delegated to the Solid Fuels Administration for War by the War Production Board, through issuance of Directive 33 on December 31, 1943.

Beehive coke.—At the beginning of the year beehive-coke prices were governed by Revised Price Schedule 77 and Maximum Price Schedule 121, together with the several amendments. On December 13, 1943, effective the same day, the Office of Price Administration issued Maximum Price Regulation 77, which was designed to bring together in one form the provisions of Revised Price Schedule 77 and of Maximum Price Regulation 121 relating to beehive-oven coke; this regulation covered all beehive-oven coke. Amendment 1 to Maximum Price Regulation 77, issued December 20, 1943, effective November 29, 1943, raised the price of beehive-furnace coke produced in the Connellsville district in hand-drawn ovens from trucked coal by $0.75 per ton to $7.75 and by $0.50 per ton to $7 for beehive-furnace coke produced in machine-drawn ovens. Amendment 2 to Maximum Price Regulation 77, issued January 4, 1944, effective November 23, 1943, raised the price of beehive coke, other than furnace coke made in the Connellsville district in hand-drawn ovens, by an amount not to exceed $1.25 per ton and $1 per ton for coke made in machine-drawn ovens. Amendment 3 to Maximum Price Regulation 77 issued January 18, 1944, effective November 29, 1943, increased the price of beehive-oven coke made in Wise County, Va., by $1 per ton.

Benzol.—Since May 1942 the Government has prohibited the use of benzol in motor fuel through issuance of General Preference Order M–137 on April 20, 1942; an amendment thereto, effective July 1, 1942, placed it under complete allocation. On July 23, 1943, this order was amended to read Allocation Order M–137 and was in force at the end of the year.

Maximum prices on benzol, toluol, xylol, and other light-oil derivatives were under the terms of the General Maximum Price Regulation, which fixed maximum prices at the individual varying highs as of March 1942, except for any of the above products going into the manufacture of aviation gasoline and synthetic rubber.

Toluol.—Throughout 1943 toluol remained under complete priority control through provisions of General Preference Order M–34, effective August 1941, and amendments thereto, effective December 30, 1941, and February 1, 1942. The order title was amended to read Allocation Order M–34 on July 23, 1943, and included all provisions set forth in previous orders.

Xylol.—Xylol and xylol-range aromatic materials derived from coal tar have been under allocation since July 1, 1942, through issuance of Amendment 1 to General Preference Order M–150; and Amendment 2 to General Preference Order M–150, issued August 29, 1942, effective the same day, further defined deliveries by kinds and for specific uses.

Naphthalene.—In 1943 naphthalene was under allocation, under terms of Conservation Order M–105 issued May 6, 1942, effective the same day.

Pyridine.—Production and distribution of pyridine in 1943 were governed by the provisions of Conservation Order M–185, effective September 1, 1942; the title was amended to read Allocation Order M–185 on July 29, 1943.

Tar.—On March 30, 1943, the War Production Board issued General Preference Order M–297, effective May 1, 1943, which provided for the allocation of crude coal tar and placed restrictions on the burning of tar and use of tar-acid oil. Ceiling prices for crude coal tar at each of the active byproduct-coke plants were established on August 20, 1943, by the Office of Price Administration in Maximum Price Regulation 447.

Ammonium sulfate and ammonia liquor.—Ammonium sulfate and ammonia liquor produced at byproduct-coke plants were under allocation throughout the year under provisions of General Preference Order M–163, issued May 30, 1942, effective June 1, 1942; maximum prices of ammonium sulfate were controlled by the terms of Maximum Price Regulation 205, issued August 17, 1942, effective August 22, 1942, and Amendment 1, issued March 15, 1943, effective March 20, 1943.

TECHNOLOGIC DEVELOPMENTS

Progress in technologic developments in 1943 was stimulated by war and directed toward solutions of wartime problems. The Bureau of Mines conducted several important studies on coal preparation, and the conclusions reached made possible the use of coals for metallurgical purposes that otherwise were not suitable because of high sulfur, ash, and phosphorus content.[1] A wider selection of coals for carbonization was made possible through technologic investigation of the chemical composition and carbonizing properties of various coals.[2] Blast-furnace requirements were studied in detail by Lowry and Mayers,[3] who emphasized the importance of coke structure and analysis. Expanded aluminum production and the scarcity of petroleum coke in 1943 aroused concern over the available supply of coke suitable for making carbon electrodes. The Bureau of Mines developed a method of producing carbon electrodes from coke made from certain low-ash coals.[4] A survey of the accomplishments of the Bureau of Mines in research work on coal during the fiscal year 1943 has been made available in the form of an annual report.[5]

POST-WAR OUTLOOK

The carbonization of coal in byproduct ovens faces an encouraging outlook in our national economy after hostilities cease. The contribution of metallurgical fuel by the beehive industry in our war program has been noteworthy; however, the economy of byproduct ovens will doubtless entirely displace the beehive ovens as a source of metallurgical fuel in future, except for emergencies. Although the future outlook for the byproduct industry is favorable, the present high production rate will not be maintained because old ovens will fail and the demands for steel will diminish. It is generally agreed that civilian requirements of steel products will not equal the present wartime demands, and this will doubtless lower the requirements of furnace coke. However, the displacement of beehive coke, the reestablishment of domestic coke markets to pre-war levels, and the increasing demands for light oil and coal-tar products point toward active markets for the byproduct industry. The potential scope of application of the light-oil and coal-tar chemicals is virtually limitless, and present-day uses will increase. The rapidly expanding plastic, synthetic rubber, aviation gasoline, pharmaceutical, and dyestuffs industries are some of the more important outlets for increasing quantities of benzol, cresols, cresylic acid, phenol, pyridine, and other products derived mainly from byproduct coking.

TABLE 1.—*Salient statistics of the coke industry in the United States in 1943*

	Byproduct	Beehive	Total
Coke produced—			
At merchant plants:			
Quantity....net tons..	14, 750, 033	(1)	14, 750, 033
Value....	$114, 280, 452		$114, 280, 452
At furnace plants:			
Quantity....net tons..	48, 992, 643		48, 992, 643
Value....	$309, 844, 677		$309, 844, 677
Total:			
Quantity....net tons..	63, 742, 676	7, 933, 387	71, 676, 063
Value....	$424, 125, 129	$51, 992, 343	$476, 117, 472
Screenings or breeze produced:

TABLE 1.—*Salient statistics of the coke industry in the United States in 1943*—Con.

	Byproduct	Beehive	Total
Coke used by producer—			
In blast furnaces:			
Quantity net tons	34,496,795	555,486	35,052,281
Value	$225,275,525	$3,677,616	$228,953,141
In foundries:			
Quantity net tons	57,140		57,140
Value	$394,972		$394,972
To make producer gas:			
Quantity net tons	884,053		884,053
Value	$5,812,963		$5,812,963
To make water gas:			
Quantity net tons	1,771,786		1,771,786
Value	$9,834,079		$9,834,079
For other purposes:			
Quantity net tons	309,297	89,553	398,850
Value	$2,293,390	$743,785	$3,037,175
Disposal of coke:			
Sold to financially affiliated corporations—			
For blast-furnace use:			
Quantity net tons	12,256,558	1,538,192	13,794,750
Value	$69,421,276	$9,426,483	$78,847,759
For foundry use:			
Quantity net tons	5,661		5,661
Value	$31,762		$31,762
For manufacture of water gas:			
Quantity net tons	502,409		502,409
Value	$3,212,936		$3,212,936
For other purposes:			
Quantity net tons	274,810		274,810
Value	$1,830,230		$1,830,230
Sold to other consumers—			
For blast-furnace use:			
Quantity net tons	4,132,286	4,710,843	8,843,129
Value	$29,995,485	$30,889,798	$60,885,283
For foundry use:			
Quantity net tons	2,217,499	326,589	2,544,088
Value	$22,557,740	$2,505,231	$25,062,971
For manufacture of water gas:			
Quantity net tons	751,982	146,682	898,664
Value	$6,028,560	$977,673	$7,006,233
For other industrial use:			
Quantity net tons	1,805,935	463,377	2,269,312
Value	$12,984,481	$3,147,955	$16,132,436
For domestic use:			
Quantity net tons	4,784,090	101,438	4,885,528
Value	$39,292,885	$621,842	$39,914,727
Disposal of screenings or breeze:			
Used by producer—			
For raising steam:			
Quantity net tons	3,068,273	28,008	3,096,281
Value	$7,465,961	$35,904	$7,501,865
To make producer or water gas:			
Quantity net tons	40,945		40,945
Value	$153,855		$153,855
For other purposes:			
Quantity net tons	576,566	6,138	582,704
Value	$1,457,429	$10,600	$1,468,029
Sold:			
Quantity net tons	1,291,909	61,192	1,353,101
Value	$3,920,076	$67,518	$3,987,594
Average receipts per ton sold:			
Furnace coke (merchant sales)	$7.26	$6.56	$6.89
Foundry coke	$10.17	$7.67	$9.85
For manufacture of water gas	$8.02	$6.63	$7.80
Other industrial coke	$7.19	$6.79	$7.11
Domestic coke	$8.21	$6.13	$8.17
Screenings or breeze	$3.03	$1.10	$2.95
Stocks on hand January 1, 1944:

Surplus gas sold or used	$1.37	$1.507	$1.454	$1.426	$1.390
Total byproducts, including breeze	$3.48	$3.117	$3.130	$3.015	$3.297

---

[1] Furnace and foundry coke only.
[2] Before 1934, figures represent general imports; beginning with 1934, they represent imports for consumption only.
[3] "For all other purposes" included under "Other industrial (including producer and water gas)."

SCOPE OF REPORT

This report contains final statistics for the byproduct- and beehive-coke industry for 1943. In accordance with usual procedure, most of the tables herein also include comparable data for 3 or 4 preceding years. In addition to the customary annual report on byproduct and beehive coke, tables are included showing the quantity and value of coke recovered from beehive breeze dumps and salient statistics of the coal-gas industry, compiled from reports by the operators to the Bureau of Mines

In addition to the coke produced in byproduct ovens, beehive ovens, and coal-gas retorts, coke is obtained in the refining of petroleum and of tar. Although tonnages of petroleum coke and coal-tar-pitch coke are very small in comparison with byproduct- and beehive-coke production, they are important in the production of carbon and graphite electrodes for the aluminum and magnesium industries. In 1943, 1,388,000 tons of petroleum coke and 111,000 tons of coal-tar-pitch coke were produced compared with 1,338,000 and 118,000 tons, respectively, in 1942.

Since, in general, only coke from byproduct and beehive ovens is adapted to blast-furnace and foundry use and since most of the coke produced is directed to these uses, the coke trade is concerned more especially with byproduct and beehive coke, and the statistics of this report are confined to these two types.

The standard unit of measurement in the coke industry is the short ton of 2,000 pounds; that unit is employed throughout this report unless otherwise specified.

COKE AND COKE BREEZE

MONTHLY AND WEEKLY PRODUCTION

Tables 3 to 7 summarize the statistics of weekly and monthly production of byproduct and beehive coke Weekly and monthly data on byproduct coke are based upon reports from producers. The monthly rate of production of byproduct coke showed a gradual upward trend in 1943 (mainly because of new oven installations placed in operation) and reached a peak of 5,555,600 tons in December. Data on weekly production indicated fluctuations in production rates and in 1943 ranged from a low point for the week ended November 6 to a peak in the week ended December 18.

Weekly production of beehive coke was estimated from records of car loadings received each week from the principal coke-carrying railroads with minor adjustments. Monthly production of beehive coke was based upon reports from producers. The monthly output of beehive coke in 1943 fluctuated from the 753,200 tons in March to 420,400 tons in June, the lowest figure since April 1941. Table 6 shows the production of beehive coke by weeks and exhibits the effects of mine stoppages in 1943, and weekly output ranged from 53,200 tons for the week ended June 26 to 177,400 tons for the week ended April 10.

---

[1] Daily average production of beehive coke before 1941 was calculated by subtracting Sundays and holidays in each month: 1941–43 daily average has been calculated by dividing the total monthly production by the total number of days in the month.

PRODUCTION BY FURNACE AND NONFURNACE PLANTS

The classification of "furnace" and "nonfurnace" or "other" plants as used in this report applies to the byproduct industry only. Furnace plants are those affiliated with the iron and steel industry, with an output that does not ordinarily enter the open market. "Nonfurnace" or "other" plants include a few plants affiliated with local iron furnaces but producing more coke than their furnaces can absorb and therefore depending chiefly on the foundry and domestic trade or on merchant sales of furnace coke for disposal of their output. This latter classification also includes plants affiliated with alkali works; low-temperature carbonization plants; and in addition a number of plants that, although not public utilities, were constructed primarily to supply city gas, which sell their coke for domestic, industrial, or metallurgical uses.

Four plants were added to the list of furnace plants in 1943—1 plant reclassified from nonfurnace and 3 new plants built to supply coke to new blast-furnace installations—which raised the number of active furnace plants to 50. Furnace plants produced 48,992,643 tons of coke in 1943, or 77 percent of the total output of byproduct coke. In the nonfurnace group, 2 plants were removed from the list of active producers in 1943—1 because operations were discontinued in the middle of 1942 and 1 because of the change in classification; however, 1 new plant that started initial operation in April was added, which resulted in a net loss of 1 plant in this group and reduced the number of active producers to 41. Nonfurnace plants supplied 14,750,033 tons of byproduct coke in 1943, and the rate of production in this group was relatively constant throughout the year.

TABLE 8.—*Number and production of byproduct-coke plants connected with iron furnaces and of other byproduct plants in the United States, 1913, 1918, and 1941–43*

Year	Number of active plants		Coke produced (net tons)		Percent of production	
	Furnace plants	Other plants	Furnace plants	Other plants	Furnace plants	Other plants
1913	20	16	9, 277, 832	3. 436, 868	73. 0	27. 0
1918	36	24	19, 220, 342	6, 777, 238	73. 9	26. 1

PRODUCTION BY STATES AND DISTRICTS

The surge in coke requirements in 1943 witnessed some interesting changes in the location of coke producers. California became an active producer of byproduct coke for the first time, and Washington produced byproduct coke for the first time since 1937. The record output of byproduct coke in 1943 was obtained from 91 active plants in 22 States; production increased in 13 States and decreased in 9 compared with 1942. The ranking producing States, in order of tonnages, were Pennsylvania, Ohio, Indiana, New York, and Alabama, which together supplied 71 percent of the total output. Of the five ranking States, all except Alabama showed increases over 1942, where the effect of four mine stoppages were not offset by the increased production capacities, and this State yielded fourth place to New York. The States that showed the largest percentages of increase over 1942 were Indiana with 11 percent; Tennessee, 8 percent; Missouri and West Virginia, each 7 percent; and Ohio, with 4 percent.

Production of behive coke increased in three States and decreased in five in 1943 when compared with 1942. Although production of beehive coke in Pennsylvania decreased 5 percent from 1942, it remained the leading producer and supplied 87 percent of the total beehive output. Production in Virginia decreased 57,197 tons and yielded second place to West Virginia, where production increased from 335,221 tons in 1942 to 423,551 in 1943. Utah, with increased new oven capacity, attained a production of 84,093 tons and more than trebled the 1942 output. Production in Kentucky increased from 1,138 tons in 1942 to 29,298 in 1943.

[1] Includes plants at Bethlehem, Chester, Philadelphia, Steelton, and Swedeland.
[2] Includes plants at Aliquippa, Champion, Clairton, Erie, Johnstown, Midland, Monessen, Neville Island, and Pittsburgh.
[3] Comprises figures from one plant each in Beaver, Bedford, Cambria, and Greene Counties.

NUMBER AND TYPE OF OVENS

Byproduct ovens.—The tremendous expansion in blast-furnace capacity in 1943 was matched by the greatest construction program in the byproduct-coke industry since 1927. A total of 953 new byproduct ovens was completed during 1943, and 5,220,610 tons were added to the annual coke-producing capacity. Three ovens failed during the year and were reported abandoned by the operators, which resulted in a net gain of 950 ovens; at the end of the year 14,253 byproduct ovens were in existence, with an annual coke capacity of 71,378,408 tons, or 11 percent over 1942. According to reports submitted to the Bureau of Mines, 528 new ovens (with an annual coke capacity of 2,644,663 tons) were under construction at the close of the year. Of the 14,253 ovens reported in existence at the end of the year 37 percent were Koppers, 39 percent Koppers-Becker, 13 percent Semet-Solvay, 9 percent Wilputte, and the remaining 2 percent of miscellaneous types.

Beehive ovens.—In the beehive industry, 2,044 ovens—500 new and 1,544 rehabilitated—were placed in operation during the year. The number of ovens abandoned totaled 673, a net gain of 1,371 ovens over 1942, which raised the total number in existence at the close of the year to 17,666, with an annual coke capacity of 11,230,396 tons. This was an increase over 1942 of 8 percent in number of ovens and 8 percent in capacity; however, the change is not significant, since operators consider certain ovens serviceable one year and not serviceable the next, according to general conditions.

[1] Comprises 63 Curran-Knowles, 8 Piette, and 3 Disco ovens.

CAPACITY OF BYPRODUCT PLANTS

The completion of new oven installations at byproduct plants during 1943 added 14,303 tons of coke per day to the potential maximum daily capacity of the industry; and at the end of the year the capacity of all ovens in existence, whether idle or active, totaled 195,557 tons per day. This represented an increase of 11 percent over the capacity at the beginning of the year and 15 percent over the pre-war figure of 170,467 tons at the end of 1940. Capacity, as thus stated, is defined as the total quantity of coke of the grade the operator aims to produce that can be obtained in a 24-hour period with all conditions favorable and all ovens active. This capacity is governed by operating, economic, and labor conditions and is subject to change from year to year, according to changes in coking time, coal mixtures, or other variables.

Table 17 shows the relationship between production and potential maximum capacity at byproduct-coke plants, by months, in 1929 and 1940–43. The maximum daily capacity was based upon data supplied by the operators in the annual reports, and therefore adjustments were made from time to time as new ovens were placed in operation. The rate of production has been maintained relatively constant during the past 2 years, except for slight fluctuations in 1943, when mine stoppages interrupted the flow of coal to the byproduct-coke plants.

[1] Capacity of all ovens in existence, whether active or idle, based upon maximum daily capacity times days in month.

QUANTITY AND COST OF COAL CHARGED

Byproduct and beehive ovens rank next to the railroads as leading industrial consumers of bituminous coal. In 1943 the quantity of coal charged into byproduct- and beehive-coke ovens surpassed the 1942 record figure by 1,610,400 tons and reached 102,460,000 tons. Of this tonnage byproduct ovens consumed 88 and beehive ovens 12 percent. The steadily increasing expansion in coal-carbonizing capacity in the byproduct industry in 1943 increased the quantity of coal used each month and reached a maximum of 7,833,300 tons in December 1943. Indications in early 1944 pointed toward even greater requirements. Pennsylvania was the leading consumer of coking coal and used 27 percent of the coal consumed in the byproduct industry and 86 percent in the beehive industry. Ohio and Indiana were large consumers of byproduct coal and used 16 percent and 12 percent, respectively, in 1943.

The total cost of coal charged into byproduct ovens increased 11 percent in 1943 compared with 1942; the total cost of coal charged into beehive ovens increased 17 percent. The increases in cost of coking coal to coke-oven operators followed the general increases in coal prices and were governed by the terms of Maximum Price Regulation 120, issued April 29, 1942, effective May 18, 1942, and subsequent amendments.

PREPARATION AND SOURCE OF COAL

Washed and unwashed.—Table 21 presents the tonnages of washed and unwashed coal used in the manufacture of byproduct and beehive coke in 1943. Coal washed, as used in this report, is defined as the separation of impurities such as dirt, shale, sulfur, and phosphorus, from raw coal by mechanical cleaning by wet or pneumatic methods. High-ash coal charged into ovens results in an even higher ash content of the coke produced and causes definite economic losses in the blast furnace.[6]

Most of the cleaning plants are at the mines, but some are at the ovens. All coal mined in Colorado, Alabama, and Washington and most of that produced in Pennsylvania, Tennessee, and Illinois and used for the manufacture of coke was washed. In 1943, 27 percent of the coal charged into byproduct ovens and 11 percent into beehive ovens was washed. The lack of mechanical cleaning equipment at small truck mines that supplied coal to beehive ovens accounted for the fact that the percentage of washed coal charged into beehive ovens was much less than for byproduct ovens.

Sources.—The geographical location of coking-coal deposits, because of its irregular and limited distribution, has vital importance to our national economy. Almost any kind of clean coal can be used for ordinary fuel, but the coke industry undoubtedly has the most stringent standards of all major coal-consuming industries. Byproduct and beehive ovens not only require coal that is relatively free from impurities, but in addition it must fuse and develop a strong porous structure when heated in ovens.

The principal sources of coking coal are Pennsylvania, West Virginia, and Kentucky, which together supplied 87 percent of all coal purchased for the manufacture of byproduct coke in the United States in 1943. Other important sources were Alabama, with 8 percent, and Virginia, Utah, Colorado, Illinois, Tennessee, New Mexico, Indiana, Washington, Georgia, and Maryland, which together furnished 5 percent.

Blending.—More and more emphasis is being placed on quality of coke, and one means of improvement is blending the coals charged.[7] This practice is designed primarily to produce, economically, coke of satisfactory quality for the use intended. It permits the use of coals that have coking properties but may be objectionable because of excessive ash, sulfur, or phosphorus and could not be used as a 100-percent charge.

Blending was practiced at 71 byproduct plants in 1943, of which 41 used high- and low-volatile coal; 22, high, medium, and low; 4, high and medium; and 4, low and medium.

The relative proportions of high-, medium-, and low-volatile coking coal purchased by byproduct-coke-plant operators has remained fairly constant during the past 3 years; and in 1943, of the 89,204,294 tons of coking coal purchased, 64 percent were high; 14 percent medium; and 22 percent low volatile.

COKE BREEZE

In the manufacture of coke there is inevitably produced a certain quantity of fines or screenings unsuitable for furnace or foundry use and in but little demand as a domestic fuel. This material, known to the trade as breeze, irrespective of whether produced at byproduct or at beehive plants, is that portion of the small coke that remains after all large sizes (usually one-half inch and over) are removed by screening or hand forking. At byproduct plants it may be defined as the next size smaller than pea coke—that is, coke passing through a ½- or ¾-inch screen, since there is no standard screen size. At beehive plants it is that coke which passes through the tines of the loading forks or the screens of the loading machines, and its dimensions therefore vary.

Table 26 indicates that in the byproduct industry uses for breeze can usually be found and the quantity wasted is negligible, but in the beehive industry the problem of finding a profitable outlet for breeze remains unsolved. As the low value per ton will not justify long rail hauls, breeze is generally used at or near producers' plants. Of the 4,789,569 tons recovered at byproduct plants in 1943, 3,685,784 tons (77 percent) were used by the producers—3,068,273 tons for steam raising and 617,511 tons for other purposes, including producer-gas and water-gas manufacture. The quantity sold by producers increased 39 percent over 1942 and totaled 1,291,909 tons.

The total quantity of beehive-coke breeze recovered declined slightly in 1943 from the 1942 figure of 151,653 tons and totaled 151,343 tons. Breeze produced per ton of coal charged averaged 3 percent in 1943 at plants actually recovering. Since but little of the breeze actually produced was recovered at beehive plants, this material was treated as waste matter or "ash" and allowed to accumulate in piles or dumps. This practice doubtless has allowed many fragments of a size large enough for domestic use to accumulate. The shortage of domestic fuel and the stimulus of high prices which pre-

[1] Yield computed by dividing production of breeze by coal charged at plants actually recovering.

[2] Included under "Undistributed."

[3] As reported; quantity produced but not used was undoubtedly greater. See Mineral Resources of the United States, 1922, pt. 2, pp. 726–727.

vailed in 1943 directed attention to the huge breeze dumps in the Connellsville region, and appreciable quantities of the material were reclaimed. The practice had assumed such proportions by the latter part of the year that the Bureau of Mines initiated a monthly canvass of the new industry, beginning in October. The Office of Price Administration established maximum prices on two sizes, ½ by 1 inch and 1 inch and over. By the end of the year there were 10 operations, and the total quantity recovered and shipped was 210,751 tons valued at $868,143 (table 27).

CONSUMPTION OF COKE

The unprecedented activity in all branches of industry throughout 1943 resulted in the largest consumption of coke ever recorded. The indicated consumption of byproduct and beehive coke in the United States was 71,406,532 tons, an increase of 1,299,314 tons over 1942. According to figures compiled by the American Iron and Steel Institute, 56,701,419 tons (79 percent) of this quantity were consumed in iron blast furnaces in the manufacture of pig iron and ferro-alloys. The remaining 21 percent was consumed in foundries, in nonferrous smelters, in water-gas plants, for other miscellaneous industrial uses, and for domestic heating.

The upward trend of fuel consumption per ton of pig iron produced continued in 1943. As shown by table 29, the quantity of coke required to make 1 ton of pig iron increased from an average of 1,791.4 pounds in 1942 to 1,800.6 pounds.

TABLE 28.—*Coke consumed in manufacture of pig iron and for other purposes in the United States, 1913, 1918, and 1940–43, in net tons*

Year	Total production	Imports	Exports	Net change in stocks	Indicated United States consumption [1]	Consumed by iron furnaces [2]		Remainder consumed in other ways	
						Quantity	Percent	Quantity	Percent
1913	46,299,530	101,212	987,395	(3)	45,413,347	37,192,287	81.9	8,221,060	18.1
1918	56,478,372	30,168	1,687,824	(3)	54,820,716	45,703,594	83.4	9,117,122	16.6
1940	57,072,134	112,550	804,095	−645,657	57,026,246	41,839,039	73.4	15,187,207	26.6

1942	70,568,944	108,819	839,582	−269,037	70 107,218	54,694,746	78.0	15,412,472	22.0
1943	71,676,063	98,127	994,607	−626,949	71,406,532	56,701,419	79.4	14,705,113	20.6

[1] Production plus imports minus exports, plus or minus decrease or increase, respectively, of net changes in stocks.

[2] From Report of American Iron and Steel Institute. Figures include coke consumed in manufacture of ferro-alloys.

[3] Data not available.

TABLE 29.—*Coke and coking coal consumed per net ton of pig iron made in the United States, 1913, 1918, and 1940–43*

Year	Coke per net ton of pig iron and ferro-alloys [1] (pounds)	Yield of coke from coal (percent)	Coking coal per net ton of pig iron and ferro-alloys (pounds calculated)	Year	Coke per net ton of pig iron and ferro-alloys [1] (pounds)	Yield of coke from coal (percent)	Coking coal per net ton of pig iron and ferro-alloys (pounds calculated)
1913	2,172.6	66.9	3,247.5	1941	1,767.8	70.0	2,525.4
1918	2,120.7	66.4	3,193.8	1942	1,822.8	70.0	2,604.0
1940	1,781.2	70.1	2,540.9	1943	1,834.3	70.0	2,620.4

[1] From Report of American Iron and Steel Institute; consumption per ton of pig iron only, excluding furnaces making ferro-alloys, was 2,172.6 pounds in 1913, 2,120.7 in 1918, 1,756.9 in 1940, 1,745.2 in 1941, 1,791.4 in 1942, and 1,800.6 in 1943.

FURNACE, FOUNDRY, DOMESTIC, AND OTHER COKE

Distribution, by major uses, of byproduct and beehive coke as reported by operators is shown in tables 30 and 31. Records on the distribution, by uses, are important because of the light they throw on the trends in coke consumption. Not all producers, especially those that sell through middlemen, can furnish precise information on the ultimate use of the portion they sell, but the Bureau of Mines does ask for the use to which that part of the output consumed by the producers is put and also for separation of the sales into the broad classification "furnace," "foundry," "domestic," and "other industrial."

Furnace coke is usually run-of-oven coke from which all fine coke or breeze has been removed. Foundry coke is ordinarily a blocky coke of maximum size much larger than furnace coke and from which all sizes under one-half to 3 inches have been screened out. Domestic coke generally includes a mixture of sizes approximately 3 inches and under, exclusive of breeze. It may result from the screening of foundry or furnace coke; or, where the principal demand is for domestic coke, it may be obtained by crushing the larger fragments. A majority of byproduct-coke plants are equipped to screen and size domestic coke, but most of the beehive plants are not so equipped.

In 1943, 37,519,071 tons (59 percent) of the byproduct-coke output were used by producers. Of this quantity, 92 percent was used in blast furnaces and the remainder (8 percent) for other miscellaneous purposes. Byproduct-coke sales for furnace use, including coke sold to financially affiliated corporations, increased 129 percent over 1942. Sales of byproduct foundry coke approximated sales in 1942 and totaled 2,217,499 tons. Byproduct coke sold for other industrial uses, including that sold for water-gas manufacture, increased 6 percent over 1942. The quantity of byproduct coke sold for domestic use decreased 20 percent.

Unlike producers of byproduct coke, who use the bulk of the output from their ovens, beehive producers in 1943 used but 8 percent of their output. Sales of beehive-furnace coke totaled 6,249,035 tons in 1943 compared with 6,429,279 tons in 1942. The pattern of sales of the beehive coke for foundry, other industrial, and domestic use in 1943 varied only slightly from that in 1942.

---

[1] Includes 57,140 tons valued at $394,972 used in foundries; 884,053 tons, $5,812,963 used to make producer gas; 1,771,786 tons, $9,834,079 used to make water gas; and 309,297 tons, $2,293,390 used for other purposes than in blast furnaces.

[2] Comprises 12,256,558 tons valued at $69,421,276 sold to financially affiliated corporations for blast-furnace use; 5,661 tons, $31,762, for foundry use; 502,409 tons, $3,212,936, for manufacture of water gas; 274,810 tons, $1,830,230, for other purposes; and 4,132,286 tons, $29,995,485, reported as merchant sales of blast-furnace coke.

[3] Includes 751,982 tons valued at $6,028,560 sold for manufacture of water gas.

[4] Included under "Undistributed."

[1] Includes 89,553 tons valued at $743,785 used for other purposes than in blast furnaces.

[2] Comprises 1,538,192 tons valued at $9,426,483 sold to financially affiliated corporations for blast-furnace use and 4,710,843 tons, $30,889,798, reported as merchant sales of blast-furnace coke.

[3] Included under "Undistributed."

[4] Includes 146,682 tons valued at $977,673, sold for manufacture of water gas.

STOCKS OF COKE AND COKING COAL

Stocks of byproduct coke at producers' plants totaled 825,613 tons on January 1, 1944, a decrease of 43 percent from stocks held at the beginning of 1943. The tonnage in stock on January 1, 1944, was the lowest since the end of 1925 and reflected the abnormal demand for all grades of byproduct coke throughout the year. The combined stocks of byproduct furnace and foundry coke at the end of 1943 totaled 538,942 tons or 32 percent less than at the beginning. Domestic coke stocks dropped 57 percent in the same period and totaled 286,671 tons.

Stocks of beehive coke held by producers are normally very small and on January 1, 1944, totaled 36,487 tons. This tonnage was nearly the same as those held on January 1, 1943, and the quantity by kinds varied only slightly.

Since the production of byproduct coke is a continuous process, adequate supplies of coking coal are essential for full operation. The four general mine stoppages in 1943 interrupted the flow of coking coal and thereby reduced the stocks at many plants to dangerously low levels. In order that plants with small stocks of coal could maintain maximum production of the vitally needed coke, the Solid Fuels Administrator, pursuant to Regulation 1, promulgated May 4, 1943, ordered the diversion of coal from other users to the byproduct coke plants. Stocks of coking coal on January 1, 1943, were sufficient for 44 days' requirements at the December 1942 rate of consumption; these decreased steadily so that by the end of the year only 25 days' requirements, based upon the December 1943 rate of consumption, remained in stock. A summary showing the quantity of coking coal on hand at the end of each month in 1943 is shown in table 35.

TABLE 32.—*Stocks of furnace, foundry, and domestic coke and of breeze in the United States on January 1, 1944, by States, in net tons*

VALUE AND PRICE

Reference has been made in previous chapters to the varying practices of coke operators financially affiliated with iron and steel plants, by which the coke sometimes is charged to the furnace department at cost and sometimes at a price that includes a percentage of profit or at the prevailing market price. For that part of the output sold, the value is the amount received for the coke, f. o. b. ovens. The total value of all coke used and sold, according to operators' reports, increased 13 percent over the 1942 figure.

According to sales data furnished by operators, average receipts per ton of byproduct coke sold in 1943 increased over 1942 as follows: Furnace $0.03, foundry $0.02, domestic $0.33, and other industrial $0.13.

Average sales realization for beehive coke in 1943 showed the following price increases per ton over 1942: $0.81 for furnace, $0.62 for foundry, $0.59 for other industrial, and $0.59 for domestic.

[1] Iron Age.
[2] Operators of hand-drawn ovens using trucked coal may charge $7 effective February 3, 1943, and $7.75 effective November 29, 1943.

SHIPMENTS BY RAIL, WATER, AND TRUCK

Methods and means of shipping coke from producing plants are shown in tables 38 and 39. Tonnages are based upon reports submitted by operators as to whether coke sold was shipped by rail, water, or truck. In the byproduct industry a large part of the coke produced is consumed close to the ovens and is not loaded for shipment. In 1943 shipments of byproduct coke totaled 26,731,230 tons or approximately 42 percent of the production. Of this tonnage 84 percent moved by rail, 7 percent by water, and 9 percent by truck. Beehive ovens are usually located at the mines, and the bulk of the beehive-coke output must be transported to points of consumption. In 1943 shipments of beehive coke totaled 7,287,121 tons, equivalent to 92 percent of the annual production. Water-borne and truck shipments constituted but 2 percent and railroad shipments 98 percent of the total coke loaded.

TABLE 38.—*Beehive coke loaded for shipment on originating railroads, waterways, and trucks in the United States in 1943, by routes, as reported by producers*

Route	State	Net tons		Percent of total
		By States	Total

DISTRIBUTION OF BYPRODUCT AND BEEHIVE COKE

The importance of metallurgical coke, the shortage of solid fuels for domestic requirements, and the problem of transportation in 1943 focused attention on coke production and distribution by uses and by geographic areas. Coke consumption by States, by uses, as shown in table 40, indicates the total quantity of coke available for consumption in each State, whether produced therein or received from other States, according to reports from producers. A comparison of the consumption by major uses, according to geographic areas, for 1941–43 is presented in table 41.

The total consumption of byproduct and beehive coke in the United States, exluding imports, amounted to 71,636,836 tons, a 2-percent increase over the previous high in 1942. The distribution of coke is widespread, and every State in the Union and the District of Columbia used coke in 1943. The total consumption of 4,962,594 tons of breeze, divided among 38 States and the District of Columbia, represented an increase of 7 percent over 1942.

Blast-furnace coke was used in 17 States in 1943, and the increased requirements by an expanded iron and steel industry resulted in a consumption of 57,629,884 tons, an increase of 4 percent over 1942. Byproduct and beehive coke used for producer-gas manufacture, water-gas manufacture, and other industrial purposes varied only slightly from the quantities so used in 1942. The quantity of coke available for domestic heating continued the downward trend started in 1940 because of diversion to the metallurgical industries and dropped 20 per cent from the 1942 total to but 4,714,960 tons. In spite of the curtailed supply of domestic coke, the quantity used by domestic consumers represented the second largest coke-consuming channel.

In New England the increase in blast-furnace coke consumption more than offset the decrease in use of foundry coke and resulted in a slight net increase in coke consumption for this area. In 1943 the expanded iron and steel industry, principally in Pennsylvania, accounted in large measure for the 2-percent increase over 1942 and 9-percent advance over 1941 in total coke consumption for the Middle Atlantic region.

Coke consumption increased in Ohio but decreased in Michigan compared with 1942. The increase in Ohio was due principally to the increased use of blast-furnace coke, whereas in Michigan the decrease was due to sharp curtailed supplies of domestic coke and a reduced consumption of blast-furnace coke.

In Illinois and Indiana blast-furnace-coke consumption increased in 1943, offset the decrease in other industrial uses, and resulted in a new high coke consumption of 12,160,807 tons. The Missouri Valley showed decreased consumption in 1943 chiefly because of curtailed domestic supplies. Total coke consumption in the Lake Dock region, in the Southeast region, and in the Southwest, Mountain, and Pacific region in 1943 all showed increases over 1942 mainly because of increased use of blast-furnace coke.

TABLE 40.—*Summary of byproduct and beehive coke and breeze consumed in each State in 1943, in net tons*

[Based upon reports from all United States producers showing destination of coke used by producer or sold in 1943. Does not include imported coke, which totaled 98,127 net tons in 1943]

EXPORTS AND IMPORTS [8]

Exports.—According to figures compiled by the Bureau of Mines from records of the United States Department of Commerce, the exports of coke from the United States in 1943 increased 18 percent over 1942 and totaled 994,607 tons. This was the highest tonnage of coke shipped outside continental United States since 1934. The increase in exports was due to shortages of metallurgical and domestic solid fuels in Canada in 1943 and to the demand for United States coke to augment the supply. Of the 994,607 tons of coke exported, Canada received 97 percent, most of which moved through the gateways of Buffalo and Michigan. Apart from Canada, the export movement of coke was small, although 9,714 tons were shipped to Brazil, and 6,466 tons to Mexico.

Imports.—Coke imports decreased 10 percent in 1943 and totaled 98,127 tons. Canada and Great Britain were the only sources from which coke was imported in 1943. Canada supplied nearly all coke imported, as the quantity furnished by Great Britain amounted to less than 1 percent.

---

[8] Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

WORLD PRODUCTION

Data on production of coke have not been available for many of the principal coke-producing countries since or immediately before the outbreak of World War II. The output of coke in Canada has increased steadily in recent years and reached a new high of 2,722,301 metric tons in 1943, a gain of 7 percent over 1942. Production in the United States in 1943 soared to a new all-time high record and totaled 65,023,091 metric tons. The figures presented in table 44 show that, in 1938, Axis nations or countries now occupied by the Axis Powers produced about 50 percent of the total world output of coke; more recent complete data are not now available.

---

[1] Gas-house coke is not included.

[2] In addition to countries listed coke is produced in Chosen and Japan, but data of production are not available.

[3] Data not available.

[4] January to August, inclusive.

[5] Excluding Sudentenland since October.

[6] In Great Britain the production of gas-house coke (including breeze), not included above, is especially important and was 13,049,139 tons in 1938.

[7] Figures for 1929 represent "hard" and "soft" coke made at collieries only—73,616 tons of "hard" coke and 769,888 tons of "soft" coke. Data for other years shown represent total "hard" coke manufactured. In addition, in 1938, 921,479 tons of "soft" coke were made at collieries.

[8] Sales of coke by Wankie colliery for year ended August 30 of year stated.

[9] Exclusive of Mexico.

GAS-HOUSE COKE

The output of gas-house coke in the United States in 1943 totaled 862,104 tons, valued at $6,745,791. The output in 1943 was 3 percent less than in 1942 and comprised 364,745 tons from horizontal retorts and 497,359 tons from vertical retorts, semi-inclined retorts, and miniature gas ovens. In 1943, gas-house coke was produced at 95 plants located in 27 States. The quantity of bituminous coal used in the manufacture of gas-house coke decreased 6 percent when compared with 1942 and totaled 1,436,216 tons valued at $8,882,543.

Data on the disposition of gas-house coke by producers in 1943 showed 394,937 tons were used at producing plants—51 percent for bench fuel, 38 percent for the manufacture of water gas, 4 percent for the manufacture of producer gas, and 7 percent for miscellaneous purposes.

Total sales of gas-house coke in 1943 amounted to 577,931 tons—90 percent for domestic heating, 5 percent for the manufacture of water gas, and 5 percent for miscellaneous industrial uses. Ordinarily about half of the annual gas-house coke production is sold for domestic heating, but the shortages of other solid fuels in 1943 resulted in an increase in sales to domestic consumers from 50 percent of the output in 1942 to 60 percent. Summaries of coal-gas operations, exclusive of gas production, are shown in tables 45 and 46.

COKE-OVEN BYPRODUCTS

SUMMARY OF BYPRODUCTS

Byproduct-coke ovens are sources of vital raw materials for many industries, including chemical, dyestuff, explosive, fertilizer, paint, pharmaceutical, plastic, petroleum, synthetic rubber, and wood preserving. The increased military and civilian requirements for the various coal byproducts stimulated recovery in 1943, and several coke plants installed additional facilities for processing crude tar and crude light oil. In addition to their importance to our national economy in times of peace and in war, the recovery of coke byproducts is both an economical and a conservational measure. For example, the value of the byproducts recovered at producing plants is estimated at more than $241,000,000; of these byproducts recovered, breeze, gas, tar, and light oil had a calorific value equivalent to 21,553,000 net tons of coal, which would have been lost had the coke been made in beehive ovens (table 48). The statistics in the following tables are confined to five general groups, some of which are further subdivided. They are: (1) Gas, the most valuable, (2) crude tar and its derivatives, (3) ammonium sulfate and ammonia liquor, (4) crude light oil and its derivatives, and (5) miscellaneous byproducts. Although the quantity of coal charged into byproduct ovens in 1943 was the highest ever recorded, the quantity of crude tar and ammonia fell short of the previous record attained in 1942, mainly because the oven operations were directed toward maximum output of coke, and high oven temperatures and shorter coking periods reduced the yields of these two products per ton of coal charged. The output of gas and crude light oil surpassed the previous record output in 1942 and attained new high levels of 960,454,518 M cubic feet and 250,511,095 gallons, increases of 2 percent each over 1942.

The total sales value of all byproduct sold (excluding the value of tar used by producers and of the breeze produced) increased 3 percent over the 1942 figure to $181,929,705 and amounted to 43 percent of the value of the byproduct coke produced.

Gas.—Other than coke, gas is the most important product of coal carbonization, if judged either by value or by heat content. Gas contributed approximately 50 percent of the total revenue derived from the sales of all byproducts in 1943, and the surplus gas sold or used had a calorific value equivalent to 12,427,000 tons of coal. Byproduct-coke ovens are by far the largest producers of manufactured gas in the United States and are an important factor in the distribution of gas and power to affiliated and neighboring industries, public utilities, and communities. The quantity of surplus gas used or sold for industrial purposes and distributed through city mains amounted to 62 percent of the output and was valued at $88,620,185. In 1943 quantities of coke-oven gas used for heating ovens increased 2 percent and that wasted 16 percent over 1942; however, the proportions of the total output used for heating ovens and wasted remained the same as in 1942 (36 percent and 2 percent). The average unit value of the surplus gas dropped slightly from $0.152 per M cubic feet in 1942 to $0.150.

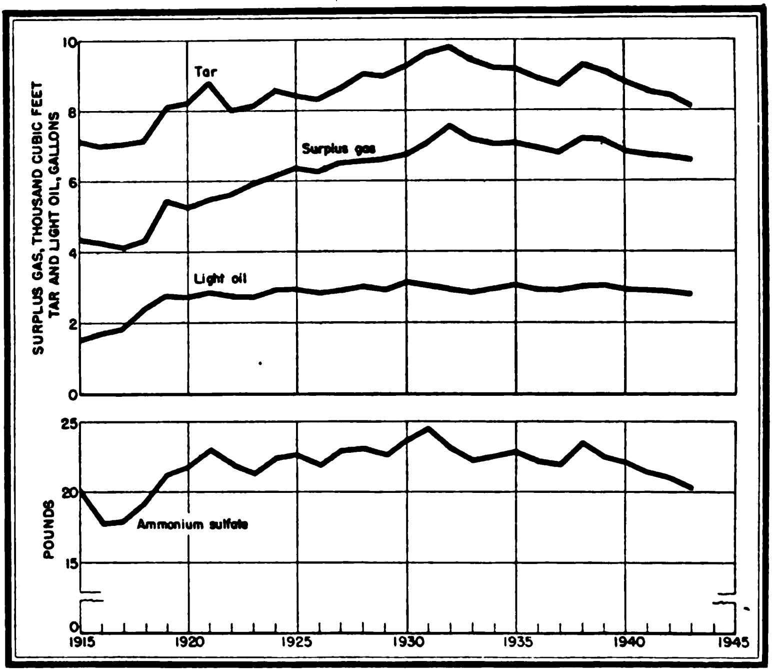

FIGURE 2.—Average yield of principal byproducts per net ton of coal carbonized in byproduct-coke ovens, 1915–43. Figures for light oil represent average at plants recovering light oil.

Crude coal tar and tar derivatives.—In recent years considerable interest has been directed toward the more efficient utilization of tar for recovering its valuable byproducts. The impetus of wartime requirements for tar acids, phenol, cresols, pyridine, naphthalene, and other products—all essential to military and civilian needs—resulted in some interesting developments in 1943. The need for tar acid oils by the expanded war industries resulted in the issuance by the War Production Board of Conservation Order M–297 on March 30, 1943, effective on and after May 1, 1943, which restricted the use of crude tar as fuel and the use of tar-acid oils. Under this order, only coal tar which had a low-boiling tar-acid content of less than 0.5 percent could be burned, and no distiller could use coal-tar oil produced on or after May 1 except for extracton of tar acids; moreover, the producers or distillers, could not deliver such coal-tar oil to any person other than distillers unless the coal-tar acids had a low-boiling tar-acid content of less than 1.5 percent. Some exceptions were later granted to a few coke plants where a satisfactory substitute fuel oil could not be obtained. In 1943 ceiling prices were established for crude coal tar through issuance of Maximum Price Regulation 447 on August 14, 1943, effective August 20, 1943, by the Office of Price Administration and Amendment 1 issued November 16, 1943, effective November 22, 1943.

The quantity of crude tar processed (topped or refined) by coke-oven operators in 1943 increased 5 percent over 1942 and was equivalent to 28 percent of the total output. The volume of crude tar sold by producers to other purchasers for refining decreased slightly in the same period and amounted to 57 percent of the total production. The increase in open-hearth operations and the scarcity of fuel oil during 1943 resulted in a 4-percent increase in the quantity of crude tar sold and used for fuel purposes. The average unit value of the crude tar sold was the same as 1942—$0.054 per gallon.

The production of creosote, the most valuable derivative obtained in tar distillation, totaled 43,552,772 gallons, and the value of sales amounted to $5,180,653.

The quantity of tar-acid oil produced at byproduct plants totaled 15,165,320 gallons, exclusive of production of tar-acid oil at plants which further refined it for recovery of phenols. The heavy tars and pitches obtained as a residue from the distillation of crude tar constitutes 50 to 80 percent of the original tar. In 1943 the quantity of pitch of tar recovered increased slightly and totaled 667,254 tons—369,015 tons of soft pitch and 298,239 tons of hard. The marketing of pitch produced at byproduct-coke plants has not been developed extensively, and in 1943 approximately 96 percent of the total output was used by the producers as fuel.

Data on production of other tar derivatives, among which are phenol, cresols, cresylic acid, road tar, and other miscellaneous derivatives, cannot be shown without disclosing individual plant operations, and only their total sales value is given.

Ammonia.—The output of ammonia (NH_3 equivalent of all forms) totaled 448,846,502 pounds in 1943, a decrease of 2,409,928 pounds from the previous peak record in 1942. Approximately 85 percent of the ammonia produced at byproduct-coke plants in 1943 was converted into sulfate; the remainder was recovered as ammonia liquor. The relatively low conversion costs and the large demands for sulfate by the fertilizer industry explain the fact that most of the ammonia produced was converted into ammonium sulfate. Production of ammonium sulfate decreased 11,068,274 pounds, but ammonia liquor (NH_3 content) increased 357,140 pounds in 1943 when compared with 1942; however, sales of both sulfate and ammonia liquor increased and resulted in a gain of 3 percent for sulfate and 1 percent for ammonia liquor.

The average unit value of ammonium sulfate in 1943 remained the same as for the previous year at $0.013 per pound; the value of ammonia liquor increased slightly and averaged $0.037 per pound.

Light oil and its derivatives.—In 1943 the production of crude light oil amounted to 250,511,095 gallons, a 2-percent increase over the previous high of 1942 Of the total output 98 percent was refined by the producers and but 2 percent was sold to other purchasers. Benzol comprises approximately 63 percent of the crude light oil, and in 1943 the combined output of all grades of benzol amounted to 153,707,106 gallons, an increase of 2 percent over 1942. The quantities of 1° and 2° benzol produced increased markedly in the same period, mainly because of the large demands of these two grades for use in the manufacture of synthetic rubber (styrene) and aviation gasoline (cumene), whereas the production of motor benzol decreased 67 percent because of restrictions on the use of benzol in motor fuel (fig. 3). The production of crude and refined toluol varied slightly from the production of the previous year and totaled 32,272,593 gallons. Nearly 86 percent of all toluol produced was 1° or nitration grade and was sold almost exclusively for the manufacture of high explosives. The output of xylol, solvent naphtha, and other light-oil products in 1943 was 8,763,927, 5,232,848, and 8,955,610 gallons, respectively, compared with 9,332,273, 5,215,617, and 9,238,117 gallons in 1942. Benzol, toluol, and xylol were under allocation the entire year, and the various allocation orders are listed under Gov-

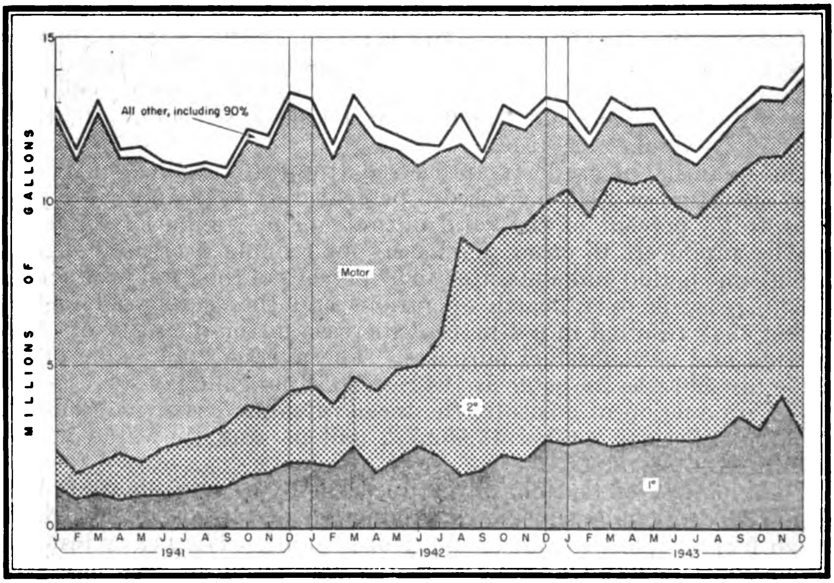

FIGURE 3.—Quantity of benzol produced at byproduct-coke plants in the United States, by grades, 1941-43.

ernment Control Measures. The average unit values of the various light-oil derivatives were approximately the same as in 1942 at $0.09 per gallon for motor benzol, $0.13 for all other grades of benzol except motor, $0.269 per gallon for toluol, $0.249 per gallon for xylol, $0.148 per gallon for solvent naphtha, and $0.10 per gallon for all other products. Ceiling prices on benzol, toluol, and xylol were under the jurisdiction of the Office of Price Administration.

Value of all byproducts sold..........	....	....	[8] 181, 929, 705	......	....

[1] Includes products of tar distillation conducted by coke-oven operators under same corporate name.
[2] Includes gas wasted and gas used for heating ovens.
[3] Refined on premises to make the derived products shown: **245,893,002 gallons.**
[4] Total gallons of derived products.
[5] Softening point less than 110° F.
[6] Softening point over 160° F. Includes some medium pitch of tar reported by one producer.
[7] Ammonium thiocyanate, cyanogen sludge, dicyclopentadiene, phenol from sources other than tar distillation, picoline, residuals, sodium cyanide, sodium prussiate, sulfur, and vented vapors.
[8] Exclusive of value of breeze production, which was $12,206,564 in 1943.

Naphthalene.—Increased war demands for naphthalene stimulated production, and output of crude naphthalene at byproduct-coke plants in 1943 increased 3 percent over 1942. Crude naphthalene at byproduct-coke plants is recovered from refining either light oil or tar. About 50 percent of the crude naphthalene produced at byproduct-coke plants, mainly from light-oil refining, is sold to large tar refineries for further processing. Most of the naphthalene recovered from coal-tar distillation is sold for consumption as such and is not refined further. The quantity of crude naphthalene sold in 1943 increased 3 percent over 1942 and totaled 98,031,058 pounds; however, the value of that sold increased 8 percent and totaled $2,088,829. Naphthalene remained under allocation in 1943.

Miscellaneous byproducts.—The increased demands and the stimulus of higher prices resulted in substantial production of miscellaneous byproducts. When compared with the major byproducts in terms of quantity and value they are small; nevertheless, they are a significant item in coking operations. The salvage of phenol from ammonia-still wastes has increased steadily; pyridine production in recent years has increased markedly; the recovery of sulfur from coke-oven gas is being more widely practiced; and all of the foregoing have assumed an importance in the war economy.

BYPRODUCT-COKE OVENS OWNED BY CITY-GAS COMPANIES (PUBLIC UTILITY PLANTS)

Byproduct-coke ovens operated by city-gas companies contributed vitally needed coke and byproducts valued at $56,440,179 to the coking industry in 1943. Although more emphasis is placed upon the production of gas of proper analysis than upon the grade of coke obtained, viewed from supply and demand for coal and coke, they are definitely a part of the byproduct industry and are included in the current statistics compiled by the Bureau of Mines. The difference in classification is maintained in the interest of those who may want information on the operations of city-gas works proper.

During 1943, 17 byproduct plants owned by city-gas companies contributed 4,005,156 tons of coke or 6 percent of the total production of the byproduct industry, an increase of 311,749 tons over 1942 when 16 plants were active. A summary of the operations of city-gas plants (public utilities) in relation to the byproduct industry as a whole is presented in the following table:

TABLE 55.—*Production of coke, breeze, gas, and byproducts in the United States at byproduct-coke plants owned by city-gas companies (public utilities* [1]*) and at all other byproduct-coke plants, 1942–43*

SUMMARY

The fuel-briquetting industry showed the effect of the war, now in its third year of United States participation, by greatly increased production in 1943; conversely, the packaged-fuel industry experienced a sharp decrease and 29 plants shut down—some permanently. This contrasting development probably is due to the fact that the fuel-briquetting industry, with comparatively few but large long-established, well-organized plants, was generally able to meet the increased demand for fuel supplies; whereas the packaged-fuel industry, with its numerous small plants (principally in retail coal yards), has suffered especially from the shortage of labor, raw fuels, and paper.[2] The paper situation has become critical owing to the enormous demand for packaging materials needed for the armed forces; however, the War Production Board is making every effort to meet 1944 paper requirements.

It is noteworthy that the fuel-briquetting industry achieved its record production with plants already in existence, utilizing reserve capacity. It would appear, therefore, that these plants can easily be adjusted to normal markets in post-war years, should history repeat itself.

Because of the nature of the materials involved, for the duration the manufacture of briquetting equipment is subject to approval and priorities by the War Production Board; used equipment, however, is not subject to priorities. No installations of new fuel-briquetting or packaged-fuel equipment were reported by the machine manufacturers in 1943. As in 1942, some manufacturers reported their plants diverted to making equipment for briquetting ferro-alloys, ores, and other war materials [3] and to perfecting their small fuel-briquetting and packaged-fuel presses for increased production and better quality of product at lower cost in anticipation of an active market after the war.

---

[1] Directories of fuel-briquetting and packaged-fuel plants operating in 1943 and names of manufacturers of equipment will be furnished on request by the Bureau of Mines, Washington 25, D. C.

Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Data on employment and principal expenses in the manufacture of fuel briquets may be obtained from the Bureau of the Census; 1939 is the latest year for which such data have been collected.

Briquets made from charcoal, wood scrap, and fruit pits are not included in the Bureau of Mines review.

Coal Heat, Use Eberling Presses for War Purposes: Vol. 44, No. 3, September 1943, p. 62.

The Solid Fuels Administration for War[4] has been actively engaged in maintaining production in all branches of the solid fuels industries, including briquetting. Utilization of Pennsylvania anthracite fines is a part of this program. Close control by the S. F. A. W. of the distribution of bituminous coal, domestic coke, and briquets has made coupon rationing of coal unnecessary thus far.

Production of fuel briquets in the United States continued the upward climb begun in 1939 and reached a record high of 2,163,998 net tons in 1943—a 24-percent increase over 1942; the output of packaged fuel, considered separately in this report, amounted to 215,605 net tons—a 15-percent decrease from 1942. The combined output in 1943 totaled 2,379,603 tons valued at $17,514,842.

Producers reported that ceiling prices prohibited profitable operation in many plants. This situation was improved on January 11, 1944, when the Office of Price Administration issued Amendment 27 to Maximum Price Regulation 121, which gave fuel-briquetting and packaged-fuel producers an opportunity to file applications before February 29, 1944, for individual increases in their maximum prices in effect on November 23, 1943. The work of the O. P. A. on coal-price control has served to avoid the enormous advance in prices of World War I, when the average value of fuel briquets at the plant in the Central States rose from $4.73 in 1916 to $6.81 in 1917 and to $8.17 in 1918; in 1940, 1941, 1942, and 1943, comparable average values of fuel briquets in the Central States were $6.95, $7.09, $7.04, and $7.44 per ton, respectively.

Records have been collected on the production of fuel briquets since 1907, when it was but 66,524 tons, with 11 plants in operation. Data on packaged fuel collected since 1935 show a phenomenal record of growth through 1940, but production has declined each year since then as a result of general wartime conditions.

Technologic developments.—Research continued in 1943, although a number of projects in the laboratory stage have been laid aside for the duration in favor of military work.

Installation of the commercial-scale briquetting press designed by R. J. Piersol[5] at the Illinois State Geological Survey has been completed, and investigations on briquetting various Illinois coals have continued with special reference to the contour of the briquet and the metallurgical composition of briquetting dies.

In 1940 Dr. Piersol reported that deduster dust and sludges from many Illinois coals contain large quantities of fusain, which is relatively smokeless. The results of his findings have been published and patented.[6]

The technical and economic study of packaged fuel by V. F. Parry,[7]

Fuels and Explosives Service of the Bureau of Mines, begun in 1941, has recently been released. Another study by V. F. Parry,[8] assisted by J. B. Goodman, on the briquetting of subbituminous coals was issued in June 1943.

FUEL BRIQUETS

Salient statistics of the fuel-briquetting industry from 1939 to 1943 are summarized in the following table. Detailed data for earlier years, beginning with 1907, are to be found in annual issues of Mineral Resources (part II) and Minerals Yearbook, which include chapters on briquetting. Production and value from 1917 to 1943, inclusive, are presented graphically in figure 1.

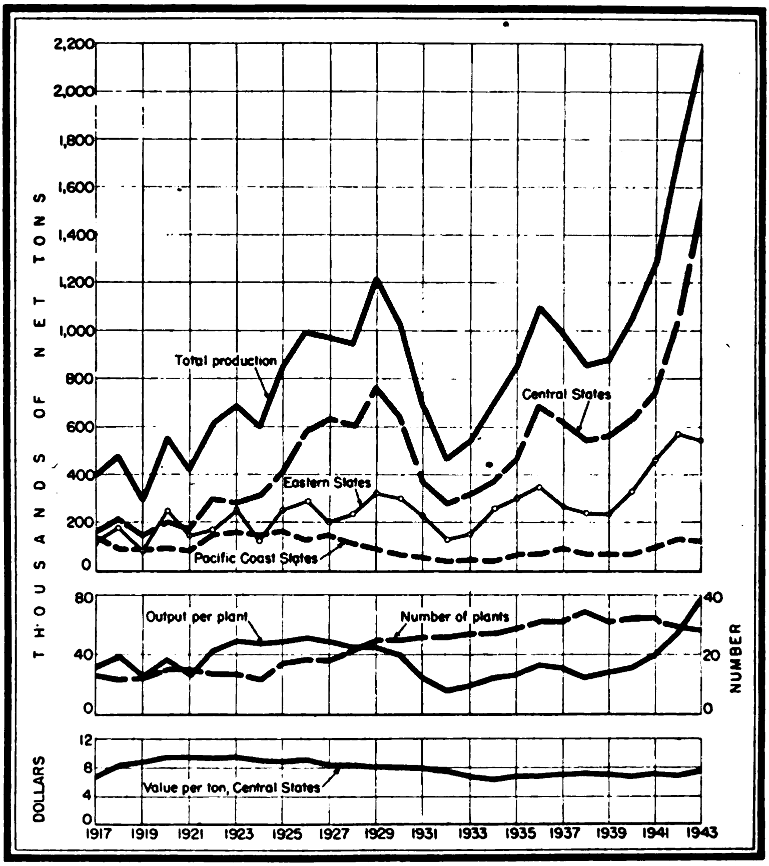

FIGURE 1.—Production of fuel briquets, output per plant, number of plants in operation, and average value per ton, f. o. b. plant (Central States), 1917–43.

Salient statistics of the fuel-briquetting industry in the United States, 1939–43

[Data regarding packaged fuel are given separately at end of this chapter]

Year	Production				Imports	Exports[1]	Consumption[2]	Value of production (thousands of dollars)	Plants in operation	Average output per plant (thousands of net tons)	Average value per net ton, f. o. b. plant		
	Eastern States	Central States	Pacific Coast States	Total							Eastern States	Central States	Pacific Coast States
	Thousands of net tons												
1939	243	574	75	892	1	13	880	5,802	31	29	$4.23	$7.15	$8.96
1940	331	652	68	1,051	------	23	1,028	6,439	32	33	3.95	6.95	8.84
1941	458	752	89	1,299	(3)	40	1,259	8,002	32	41	4.21	7.09	8.36
1942	565	1,048	135	1,748	(3)	104	1,644	11,266	30	58	4.56	7.04	9.69
1943	545	1,493	126	2,164	(3)	175	1,989	15,148	28	77	5.04	7.44	10.26

[1] Exports reported separately by U. S. Department of Commerce beginning with 1937.
[2] Production plus imports minus exports.
[3] Less than 1,000 tons.

Production.—The output of fuel briquets in 1943—2,163,998 tons valued at $15,148,109—again topped all previous records and represented a 24-percent increase in tonnage and a 35-percent increase in value over 1942. The increased activity in 1943 reveals the efforts of the industry to meet increased fuel demands in the national emergency. Production in 1943 stepped up to about two-thirds of the annual capacity, reported by the operators as approximately 3,164,000 net tons.

Briquets were produced in 14 States; Wisconsin again led with more than a million tons—half of the total production—followed in order by West Virginia, Missouri, and Pennsylvania. In Missouri three plants produced a total of 188,736 tons, valued at $1,236,829. Output for the 12 States (other than Wisconsin and Missouri) that produced briquets in 1943 cannot be shown separately without revealing individual plant data.

In the Central States—representing two-thirds of the total production—marked increases over 1942 were shown by Michigan, Missouri, Illinois, and Wisconsin, in the order named.

Packaging in cartons and bagging of bulk briquets at the plants, reported by 13 operators, are merchandizing features only, used for convenience and cleanliness in the delivery of the fuel.

Production of fuel briquets in the United States, 1942–43

	1942			1943				
							Change in 1943, percent	
	Plants	Net tons	Value	Plants	Net tons	Value	Tonnage	Value
Eastern States	3	565,675	$2,580,934	4	544,786	$2,746,109	−3.7	+6.4
Central States	23	1,047,747	7,378,165	21	1,493,368	11,110,885	+42.5	+50.6
Pacific Coast States	4	134,878	1,306,942	3	125,844	1,291,115	−6.7	−1.2
	[1] 30	1,748,300	11,266,041	[1] 28	2,163,998	15,148,109	+23.8	+34.5

[1] 1942: 10 plants in Wisconsin; 3 in Missouri; 2 each in California, Illinois, Michigan, Nebraska, and West Virginia; and 1 each in Arkansas, Minnesota, North Dakota, Oregon, Pennsylvania, Washington, and Wyoming; 1943: 10 plants in Wisconsin; 3 in Missouri; 2 each in Illinois, Michigan, and West Virginia; and 1 each in Arkansas, California, Massachusetts, Minnesota, Nebraska, North Dakota, Oregon, Pennsylvania, and Washington.

The enormous supplies of bituminous slack at Lake ports have made Wisconsin the nucleus of the briquetting industry. Lake shipments of coal to American docks on Lake Superior were nearly 15 percent greater in 1943 than in the preceding year.

Production of fuel briquets in Wisconsin, 1938–43

Year	Plants	Net tons	Value	Year	Plants	Net tons	Value
1938	10	422;281	$3,085,873	1941	10	535,457	$3,870.077
1939	10	430,554	3,158.859	1942	10	750,417	5,498,748
1940	11	487,574	3.440,676	1943	10	1,070,857	8,228,671

Other large plants are located at coal mines, principally in West Virginia and Pennsylvania, and smaller operations at petroleum refineries and gas plants, mainly in the Pacific Coast area.

As briquets are used almost entirely for domestic space heating, production is normally highly seasonal; but in 1943 production was fairly constant throughout the year, indicating anticipated demand. Twenty-three of the 28 active plants, which operated every month in 1943, produced 97 percent of the total; only 1 plant was active less than 9 months.

According to the Weather Bureau,[9] temperatures in January averaged below normal in the northern third of the country, and extremely cold weather prevailed in February in the North Central States.

Monthly production of fuel briquets in the United States, 1941–43, in net tons

Month	1941	1942	1943	Month	1941	1942	1943
January	135,532	170,991	187,201	August	109,487	112,434	204,424
February	118,596	122,083	192,201	September	107,257	139,699	205,979
March	85,728	93,668	188,500	October	120,197	204,665	205,118
April	27,252	102,514	133,531	November	143,339	177,938	179,564
May	82,723	145,792	121,027	December	137,166	197,982	204,299
June	105,307	146,389	153,854				
July	126,022	134,145	188,300		1,298,606	1,748,300	2,163,998

Value.—As sales realizations on briquets in the scattered producing centers vary considerably, an average value per ton for the entire industry has doubtful significance, because of the different conditions under which briquets are manufactured and sold. The most important factors that influence the value per ton realized at any plant are costs of raw materials and labor and prices of competing fuels; hence, the trend of fuel-briquet prices in the past 5 years is indicated best in this review by the average values in the Eastern, Central, and Pacific Coast States, as shown in the last three columns of the foregoing table of salient statistics. These are the values received by producers for the total product (exclusive of delivery charges) and not the prices paid by consumers—retail prices in certain cities are shown in a separate table. Some plants are distant from the markets they serve; and transportation charges and the margin of the wholesaler or retailer, sometimes both, must be added to the value at the plant.

The total value of fuel briquets manufactured in 1943 was $15,148,109, f. o. b. plant—an increase of $3,882,068 or 35 percent over 1942.

---

[9] Baldwin, J. L., The Weather of 1943 in the United States: U. S. Dept. of Commerce Monthly Weather Review, vol. 71, December 1943, pp. 198–199.

Prices.—The following monthly fuel-briquet prices, available for 16 cities for 1943, except as otherwise indicated, are based upon cash delivery in 1-ton (2,000-pound) lots for retail sales to household consumers at the curb or into the customer's bin (without extra handling or additional charge). Owing to war conditions, there have been changes from month to month in the fuel-briquet market in 1943, which have affected the comparability of the prices published monthly by the Bureau of Labor Statistics. In such instances comparable prices for the preceding month are shown in footnotes to the table.

[2] Comparable July price, $14.06.
[3] Includes 2 percent sales tax.
[4] Includes 3 percent sales tax.
[5] Comparable March price is $10.49.
[6] Comparable July price is $10.78.
[7] Comparable August price is $11.08.
[8] Comparable March price is $9.11.
[9] Data not available.
[10] Price per ton of 2,240 pounds.

Number of plants.—Twenty-eight briquetting plants reported production in 1943, and all but one (in Massachusetts) were also active in 1942. In March 1943 the Binkley Coal Co. leased its briquetting plant at Kansas City, Mo., to the Universal Coal Washing Co., which took over operations as lessee. No new plants went into production in 1943. Ten plants were idle in 1943, of which 4 were active and 6 idle in 1942. Four plants went out of business during the year. Two of these (the Fuel Blox Corporation, at Omaha, Nebr., and the California Fuel & Utilities, Inc., at Compton, Calif.), which were active in 1942, had been using petroleum coke as raw fuel; and two had been idle for several years.

Five plants were reported under construction in 1943, but of these only two appeared to be near the commercial-production stage. These were the plant of the Ecco Manufacturing Co., formerly of Providence, R. I. (purchased by the American Briquet Co., moved to the site of the Lincoln anthracite culm bank near Pine Grove, Schuylkill County, Pa., and scheduled to start operations in January 1944 [10] as the Ecco Manufacturing Co., subsidiary of the American Briquet Co.), and the plant of Western Carbon & Chemical, Inc., at Minot, N. Dak., to start manufacturing briquets from lignite char about July 1944, recovering valuable byproducts in the process.

---

[10] Saward's Journal, New Anthracite Briquet Plant: Vol. 26, No. 50, March 11, 1944, p. 611.

Fires were reported by two operators—the Coal Processing Corporation, at Buckner, Ill., and the St. Louis Package Fuel Co., St. Louis, Mo.

Size of plants.—The total annual capacity of the 28 active plants was approximately 3,164,000 tons and the production 2,163,998 tons or about 68 percent of their possible tonnage in 1943. Of the 12 plants reporting annual capacities of over 100,000 tons, 7 produced well over 100,000 tons each in 1943. The average output of the individual plants increased 33 percent—from 58,000 in 1942 to 77,000 in 1943. Twenty-three plants operated every month in 1943 and produced 2,101,771 tons (97 percent of the total).

The largest production at any one plant in 1943 was reported by the Stott Briquet Co., located at the coal docks on Lake Superior, followed in order of production by the Berwind Fuel Co. plant at Superior and the United Coal & Dock Co. plant at Milwaukee.

Classification of briquetting plants in the United States, 1942-43, by size of output and annual capacity

Output (net tons)	Plants		Annual capacity (net tons)	Plants	
	1942	1943		1942	1943
Less than 2,000	2	2	Less than 5,000	1	1
2,000 and less than 5,000	3	2	5,000 and less than 10,000	2	2
5,000 and less than 10,000	5	2	10,000 and less than 25,000	7	6
10,000 and less than 25,000	5	5	25,000 and less than 100,000	9	7
25,000 and less than 100,000	9	10	100,000 and less than 200,000	7	8
100,000 and over	6	7	200,000 and less than 400,000	2	1
			400,000 and over	2	3
	30	28		30	28

Raw fuels.—Bituminous slack, either alone or in combination with other fuels, was used at 20 plants in 1943 and represented 65 percent of the total production; anthracite briquet production has increased over 1942; and production of briquets made of other raw fuels decreased, principally because of withdrawal of petroleum coke from the market for domestic purposes [11] and the labor shortage in the lignite mines serving the briquetting plant at Dickinson, N. Dak. Production of briquets at plants at Lake Superior docks increased 56 percent over 1942; the next largest increase in production was at plants near bituminous-coal mines in Illinois and mines in Arkansas that produced semianthracite.

Six operators reported washing the raw fuel before its manufacture into briquets.

Classification of fuel-briquetting plants in the United States in 1943, by kinds of raw fuel used

Kind of raw fuel used:	Plants
Anthracite and semianthracite fines	6
Mixture of anthracite and bituminous coal	6
Mixture of anthracite, bituminous coal, and petroleum coke [1]	1
Bituminous:	
Low-volatile	14
High-volatile	1
Semicoke (lignite char)	1
Residual carbon from pyrolysis of natural gas	1
Residual carbon from manufacture of oil gas	2
	[2] 32

[1] Relatively small tonnage of petroleum coke of a type exempt from wartime allocation.

[2] 4 plants made 2 kinds of briquets; hence, the sum of these items exceeds the total number of plants.

---

Raw fuels used in making fuel briquets in the United States, 1942–43

Raw fuel	Net tons		Percent of total	
	1942	1943	1942	1943
Anthracite and semianthracite culm and fine sizes	386,947	592,050	23.4	28.5
Bituminous slack	1,077,474	1,341,013	65.3	64.6
Residual carbons from oil-gas manufacture and natural-gas pyrolysis; petroleum coke;[1] and semicoke (lignite char)	187,207	143,381	11.3	6.9
	1,651,628	2,076,444	100.0	100.0

[1] Relatively small tonnage of petroleum coke of a type exempt from wartime allocation.

Production of fuel briquets, 1942–43, grouped according to location of plants with reference to supply of raw fuel

Location of plant	1942		1943		Change in 1943	
	Plants	Production (net tons)	Plants	Production (net tons)	Net tons	Percent
At or near Lake Superior, Lake Michigan, or Lake Huron coal docks:						
Lake Superior	4	443,880	4	691,407	+247,527	+55.8
Lake Michigan	7	338,556	7	443,376	+104,820	+31.0
Lake Huron	1		1			
	12	782,436	12	1,134,783	+352,347	+45.0
At or near coal mines:						
Eastern States	3	565,675	3	544,671	−21,004	−3.7
Central States	6	223,860	6	320,492	+96,632	+43.2
	9	789,535	9	865,163	+75,628	+9.6
At or near petroleum refineries and oil- and natural-gas plants:						
Central States	1	163,294	1	153,354	−9,940	−6.1
Pacific Coast States	5		3			
	6	163,294	4	153,354	−9,940	−6.1
At other locations:						
Eastern States			1	10,698	−2,337	−17.9
Central States	3	13,035	2			
	[1] 3	13,035	[2] 3	10,698	−2,337	−17.9
Total United States	30	1,748,300	28	2,163,998	+415,698	+23.8

[1] Jackson, Mich., and Omaha, Nebr.
[2] Fall River, Mass., Jackson, Mich., and Omaha, Nebr.

Binders.—Asphaltic pitch continues to be the preferred binder in briquetting coal and coke. Approximately 124,000 tons of asphaltic types and small quantities of starch and coal-tar pitch were used in 1943 in the manufacture of fuel briquets. The use of asphalt or tar products in briquetting has not been restricted by the Petroleum Administration for War, although their use for certain other purposes has been curtailed for the duration.

No operators reported recarbonization of briquets to drive off smoke after leaving the presses. Whether or not the finished product will be of the smoky type depends primarily on the type of raw fuel used.

Classification of briquetting plants in the United States in 1943, by type and percentage of binder used

Type of binder	Plants	Production of fuel briquets		Ratio of binder to raw fuel (by weight)	Plants	Production of fuel briquets	
		Net tons	Percent of total			Net tons	Percent of total
Asphaltic pitch	22	1,796,838	83.0	Less than 5 percent	4	234,747	10.8
Asphaltic and coal-tar pitches	1	251,349	11.6	5 and less than 7 percent	13	829,953	38.4
Asphalt and starch	1			7 and less than 9 percent	6	983,487	45.4
Starch	[1] 2			9 percent and over	2		
No binder	[2] 3	115,811	5.4	No binder	[2] 3	115,811	5.4
	[1] 29	2,163,998	100.0		28	2,163,998	100.0

[1] 1 plant changed from starch to asphalt binder in 1943; hence, the sum of these items exceeds the total number of plants.

[2] 2 plants use residual carbon from manufacture of oil gas, and 1 uses bituminous coal as raw fuel.

Weight and shape.—Pillow-shaped briquets (under 5 ounces, with one exception), made at 23 plants continue to be the most popular in the United States.

Prevailing weight of briquets produced in the United States in 1943

Weight (ounces)	Plants	Production		Weight (ounces)	Plants	Production	
		Net tons	Percent of total			Net tons	Percent of total
Less than 2	3	58,054	2.7	6 and under 10	----------	----------	----------
2 and under 3	11	1,138,159	52.6	10 and under 16	1	99,949	4.6
3 and under 4	7	679,681	31.4	16 and under 25	2		
4 and under 5	4	188,155	8.7				
5 and under 6	----------	----------	----------		28	2,163,998	100.0

Shape of fuel briquets produced in the United States, 1942–43

Shape	1942			1943		
	Plants	Production		Plants	Production	
		Net tons	Percent of total		Net tons	Percent of total
Pillow	24	1,250.360	71.5	23	1,668,557	77.1
Cylindrical	3	478,906	27.4	3	495,441	22.9
Cube	4	19,034	1.1	2		
	[1] 31	1,748,300	100.0	28	2,163,998	100.0

[1] 1 plant made both pillow and cube shapes; hence, the sum of these items exceeds the total number of plants active in 1942.

Shipments.—It is not possible to show the shipments from each State because there are only one or two producers in each producing State except Wisconsin and Missouri, and the operations of individual companies would thus be revealed. For a graphic presentation of the centers of production, with corresponding States of destination for 1928 and 1936, see Minerals Yearbook, 1937 (p. 965, fig. 65).

Shipments of fuel briquets of domestic manufacture, 1942–43, by States of destination, as reported by producers, in net tons [1]

State	1942	1943	State	1942	1943
Arkansas	376	215	Nebraska	35, 111	38, 693
California	17, 798	11, 093	New Hampshire	2, 551	2, 565
Connecticut	1, 544	1, 558	New Jersey	1, 139	2, 149
Delaware	516	345	New York	26, 097	31, 158
District of Columbia	520	644	North Carolina	12, 894	12, 775

Missouri	172, 269	202, 562	Wisconsin	317, 627	425, 285
Montana	73		Wyoming	409	
				1, 600, 300	1, 970, 146

[1] Shipments include resales that might have been shipped to Canada or to other States of destination. For official export statistics see table "Briquets exported from the United States, 1942–43, by countries of destination and customs districts."

Generally rail movement represents shipments to considerable distances, and shipments by truck represent local and nearby consumption. As indicated in the table,[12] virtually all tonnages move by rail from the Eastern States, over three-fourths by rail from the Central States, and the greater portion by truck from the Pacific Coast States.

Direct shipments of fuel briquets by rail and truck, 1942–43, as reported by producers, in net tons [1]

Produced in—	1942			1943		
	Rail	Truck [2]	Total	Rail	Truck [2]	Total
Eastern States	550, 220	16, 244	566, 464	527, 476	16. 846	544, 322
Central States	829, 858	212, 584	1, 042, 442	1, 193, 399	295, 647	1, 489, 046
Pacific Coast States	27, 746	88, 434	116, 180	22, 646	85, 751	108, 397
Total United States	1, 407, 824	317, 262	1, 725, 086	1, 743, 521	398, 244	2, 141, 765

[1] Includes shipments outside the United States.
[2] Includes local deliveries.

Imports and exports.—The quantity of fuel briquets imported into the United States before 1922 was negligible. The anthracite shortages of 1922–23 and 1925–26, however, created a demand for European briquets (mostly from Germany, Belgium, and France and mainly for consumption in the anthracite-consuming States), which in 1926 reached a record of 123,593 net tons. Imports continued at a comparatively high level in the following years through 1932, when they amounted to 80,288 tons, but thereafter they dropped sharply and since the beginning of the war in September 1939 have virtually ceased. Figures for imports of briquets since 1919, the first year of record, are included in annual volumes of Mineral Resources and Minerals Yearbook.[13]

---

[12] Beginning of series (rail and truck shipments) 1938 Minerals Yearbook, 1939, p. 918; 1939–40, Minerals Yearbook, Review of 1940, p. 921; and following Yearbooks.

Briquets (coal and coke) and other composition coals for fuels imported for consumption in the United States, 1939–43

Year	Net tons	Value	Year	Net tons	Value
1939	1, 344	$5, 752	1942	334	$1, 739
1940	------	------	1943	196	1, 151
1941	162	791			

Wartime fuel requirements are shown by the table of exports.[14] Shipments to Canada in 1943 amounted to 174,774 tons, an increase of 69 percent over 1942. Exports to other countries were negligible in 1943.

[1] In addition to countries listed, briquets are produced in Canada and New Caledonia, but data on output are not available.

[2] Data not available.

[3] Data for year ended March 31 of year stated.

[4] Includes packaged fuel as follows—1937: 132,482 tons; 1938: 146,012 tons; 1939: 195,504 tons; 1940: 258,105 tons; 1941: 244,797 tons; 1942: 229,560 tons; 1943: 195,592 tons.

[5] Totals incomplete; they represent sum of figures given in table only.

PACKAGED FUEL

Packaged fuel is the trade name applied by the industry to a combination of briquetting and packaging of screenings compressed into 3- or 4-inch cubes and wrapped (six or eight in a package) in sturdy paper and sealed with gummed tape. The first plant producing this type of fuel was started in Detroit in the fall of 1932 by the Johnson Coal Cubing Co.[16]

Packaged fuel differs from fuel briquets. Fuel briquets must be tough and stand handling and rehandling over long distances with a minimum of degradation; be waterproof, weatherproof, and smokeless or nearly so; and hold together in the fire until nearly consumed. Packaged fuel does not need to meet all these requirements, as it is designed primarily for local or nearby consumption.

Various types of coal or coke screenings are mixed, generally with a neutral binder, to form the packaged-fuel cubes. The neat, tightly wrapped cubes make a package that withstands weathering fairly well, reduces breakage, and provides a relatively clean fuel.

The growth in popularity of packaged fuel has been due largely to its convenience and cleanliness in handling and to the fact that it may be purchased in less-than-ton lots, thus serving both seasonal and extra-seasonal needs of householders. During the recent periods of coal shortages it served to tide over customers awaiting replenishment of dealers' coal stocks.

---

[16] Eberling, C. M., "Packaged Fuel" Opens New Market For Use of Screenings: Coal Heat, vol. 25, No. 4, April 1934, pp. 42, 44.

The phenomenal growth of this industry from 1935 through 1940 and its decline since then as a result of the war are illustrated strikingly in figure 2.[17] The demand for packaged fuel, however, has not declined and could be met only in part in 1943 because of the industry's inability to make it. Scarcity and high costs of labor, raw fuels, and paper[18] have combined to reduce the volume of production, closing down many plants and forcing the liquidation of others.

Manufacturers of packaged-fuel machinery reported no sales of new presses in 1943, but used machinery has been installed at a number of plants.

Fires severely damaged three plants in 1943, which indicates the advisability of fireproof structures for housing the equipment and care in storing raw fuels and binder materials.

Processes.—No new presses or types of machinery were reported in use in 1943 by the packaged-fuel industry. In 1943, 66 of the 72 operators used the Eberling process;[19] 4 operators used Leemon[20] packaged-fuel equipment; 2 used Glenn-Smith[21] equipment; and the Johnson Coal Cubing Co.,[22] of Detroit, Mich., uses a process and equipment of its own design. Two plants used both Eberling and Leemon equipment.

In 1939 the Viking Machinery Co., of Jackson, Mich., developed a process and machine, virtually automatic throughout, for making packaged fuel. No plants in the United States are now equipped with this machinery; five contracts for such installations in the States were canceled in 1941 owing to priorities and the paper shortage.

Salient statistics of the packaged-fuel industry from 1939 to 1943 are summarized in the following table.

Salient statistics of the packaged-fuel industry in the United States, 1939–43

[Data regarding fuel briquets are given separately at beginning of this chapter]

Year	Production (thousands of net tons)			Value of production (thousands of dollars)	Plants in operation	Average output per plant (thousands of net tons)	Average value per net ton, f. o. b. plant	
	Eastern and Pacific Coast States	Central States	Total				Eastern and Pacific Coast States	Central States
1939	9	207	216	1,867	103	2	$9.69	$8.62
1940	8	277	285	2,392	106	3	10.12	8.36
1941	10	260	270	2,472	103	3	10.95	9.09
1942	8	245	253	2,540	89	3	10.74	10.02
1943	[1] 5	211	216	2,367	72	3	[1] 11.55	10.96

[1] Eastern States; no packaged-fuel production in Pacific Coast States in 1943.

Production and value.—The 72 active plants in 1943 produced 215,605 net tons with a value of $2,366,733 (see fig. 2). Production decreased 15 percent from 1942 and the total value 6.8 percent. Output declined in 9 of the 12 producing States; of the three largest—Michigan, Wisconsin, and Minnesota, in the order named—Wisconsin and Minnesota showed increases in production over 1942.

Nebraska	1	(1)	(1)	1	(1)	(1)
Ohio	22	45,228	456,896	16	33,341	363,153
Wisconsin	9	41,203	398,263	9	56,839	599,541
Undistributed [2]		7,301	79,500		7,518	84,582
Total Central States	82	245,465	2,458,678	67	210,635	2,309,348
Eastern and Pacific Coast States	[3] 7	7,583	81,409	[4] 5	4,970	57,385
Total United States	89	253,048	2,540,087	72	215,605	2,366,733

[1] Included under "Undistributed"; Bureau of Mines not at liberty to publish figures.
[2] Includes States entered as "1" above.
[3] Maine, 2; Pennsylvania, 1; Virginia, 3; and Washington, 1.
[4] Maine, 1; Pennsylvania, 1; and Virginia, 3; none in Pacific Coast States in 1943.

The values do not represent the price per ton to the consumer, as some plants sell both to retailers and consumers, but rather the average per ton received by producers on the total product (exclusive of delivery charges). The value at the plant comprises cost of coal at the mine, freight rate, direct and indirect manufacturing costs, and profit.

A large part of the business is conducted on a pick-up or cash-and-carry basis; and in Cleveland, for example, eleven 14-pound packages are so sold for $1, an average sales realization of about $13 a ton. Naturally operators prefer business of this type.

Average value received per net ton of packaged fuel in 1942–43, by States [1]

State	1942	1943	State	1942	1943
Illinois	$12.05	$12.48	Ohio	$10.10	$10.89
Indiana	10.11	10.11	Virginia	10.06	11.27
Michigan	9.74	10.57	Wisconsin	9.67	10.55
Minnesota	11.45	12.56			

[1] Includes only those States where there were 3 or more plants in both years.

Thirty-nine of the 72 plants active in 1943 operated each month of the year, producing 79 percent of the total production; 28 operated from 6 to 11 months, inclusive; and 5 less than 5 months.

Monthly production of packaged fuel in the United States in 1941–43, in net tons

Month	1941	1942	1943	Month	1941	1942	1943
January	39,594	33,924	27,106	August	10,184	9,346	9,286
February	37,727	29,360	23,434	September	17,422	18,519	18,973
March	40,893	26,779	24,908	October	27,183	30,378	21,967
April	17,592	19,353	18,252	November	30,506	26,361	22,335
May	6,318	14,068	11,965	December	30,296	27,739	21,131
June	5,028	9,533	8,476				
July	7,101	7,688	7,772		269,844	253,048	215,605

Number of plants.—In 1943 the number of plants producing packaged fuel dropped to 72, the lowest since 1937. Sixty-seven of these were also active in 1942. One-third of the total active plants are concentrated in the Detroit and Cleveland areas. Five operations were under new ownership in 1943; of these four reported production on a small scale, and 1 expected to start production in January 1944.

Activity in number of packaged-fuel plants, 1938–43

Year	Active	New	Idle	Out of business	Year	Active	New	Idle	Out of business
1938	76	16	8	1	1941	103	7	8	14
1939	103	29	11	9	1942	89	4	16	8
1940	106	16	15	14	1943	72	[1] 5	[2] 23	[3] 9

[1] 3 in Michigan, and 1 each in Ohio and Wisconsin; all but 1 active in 1943.

[2] 8 in Michigan, 6 in Ohio, 3 in Wisconsin, 2 in Indiana, and 1 each in Iowa, Maine, Missouri, and Washington; 9 of these were also idle in 1942.

[3] 3 in Michigan, 2 in Illinois, and 1 each in Iowa, Minnesota, Ohio, and Wisconsin; 4 of these were active in 1942.

Size of plants.—The average annual production per plant increased from 2,800 tons in 1942 to 3,000 tons in 1943. According to their reports, the 72 active operations (had circumstances permitted) could have produced more than twice the total 1943 output. The Johnson

Coal Cubing Co. of Detroit, followed closely by the Cleveland-Cliffs Iron Co. of Green Bay, Wis., was the largest producer in 1943.

Classification of packaged-fuel plants in the United States, 1942–43, by size of output and annual capacity

Output (net tons)	Plants 1942	Plants 1943	Annual capacity (net tons)	Plants 1942	Plants 1943
Less than 500	[1] 20	[2] 19	Less than 5,000	52	48
500 and less than 1,000	14	12	5,000 and less than 10,000	21	13
1,000 and less than 3,000	38	28	10,000 and less than 15,000	5	4
3,000 and less than 5,000	6	3	15,000 and less than 25,000	6	5
5,000 and less than 10,000	7	5	25,000 and less than 40,000	4	1
10,000 and less than 25,000	3	3	40,000 and less than 60,000		
25,000 and over	1	2	60,000 and over	1	1
	89	72		89	72

[1] 1 of these began operations in the fall of 1942.
[2] 2 of these began operations in the fall of 1943.

Raw fuels.—Packaged fuel made of petroleum coke has virtually disappeared from the market owing to restrictions on its use as a domestic fuel.[23]

Thus far, there is no record of commercial production of packaged fuel utilizing Pennsylvania anthracite fines; however, it is understood that packaged fuel made of a mixture of Pennsylvania anthracite and bituminous slack is being favorably considered by the coal industry.

In 1943, about 158,000 tons (74 percent of the total raw fuels) were shipped-in slack from the mines and from the Lake docks; the remainder represents yard screenings. Eighteen of the 72 operators used shipped-in slack exclusively, 30 used yard screenings, and 24 used both shipped-in slack and yard screenings; in 1942, 35 operators used shipped-in slack exclusively.

Cubes measuring 3 to 3¾ inches were made at 56 packaged-fuel plants; and 4-inch cubes were made at 21 plants.

Of the 72 active plants 27 reported wrapping the cubes by machine, 13 by hand, and 32 a combination of machine and hand wrapping. Sixty-six plants wrap 6 cubes to a package, 5 plants wrap 8 to a package, and only 1 reported a package of 4 cubes. Fifty-four plants make up packages weighing under 11 pounds, and 23, packages of 11 to 16 pounds; of these, 5 plants make up packages of two weights.

Only 1 plant reported sales of packaged fuel in bulk—unwrapped—amounting to less than 100 tons.

Raw fuels used in making packaged fuel in the United States, 1942–43

Raw fuel	1942 Plants	1942 Net tons	1943 Plants	1943 Net tons
Bituminous (low-volatile)	79	210,761	69	206,059
Bituminous (high-volatile)	3	4,655	2	
Arkansas semianthracite	2	34,969	2	6,613
Petroleum coke	10		[1] 2	
	[2] 94	250,385	[2] 75	212,672

[1] These plants reported a relatively small tonnage of petroleum coke of a type exempt from wartime allocation.
[2] In 1942, 5 plants made more than 1 kind and 2 used mixtures of these fuels; in 1943, 1 plant made 2 kinds and 2 plants used mixtures of these fuels. Hence, the number of the items exceeds the total number of active plants in the respective years.

---

[23] Coal Dealer, War Production Board Freezes Stocks of Petroleum Coke: Vol. 39, No. 7, November 1942, p. 23. War Production Board, Petroleum Coke Conservation Order M-212, March 1943.

Binders.—Cornstarches were used as binder by 68 plants which produced 80 percent of the total production in 1943; of these, 15 reported using 10 to 14 pounds, inclusive, of starch binder per ton of raw fuel, 32 used 15 pounds per ton, 19 used 16 to 20 pounds, inclusive, and 2 reported using over 20 pounds of binder per ton. Portland cement, in proportions from 50 to 65 pounds per ton, was used as binder by 3 plants, representing less than 1 percent of the total production. Asphalt, about 100 pounds per ton, was used by 2 plants.

About 1,900 tons of starch and 44 tons of cement were used by packaged-fuel operators in 1943.

Classification of packaged-fuel plants in the United States in 1942–43, by type and percentage of binder used

Type of binder	Plants 1942	Plants 1943	Ratio of binder to raw fuel (by weight)	Plants 1942	Plants 1943
Starch	82	67	Less than 0.5 percent		
Starch and cement	2		0.5 and less than 1 percent	65	57
Starch and asphalt	1	1	1 and less than 2 percent	19	11
Cement	2	3	2 and less than 3 percent	1	1
Asphalt	2	2	3 and less than 5 percent	2	2
			5 percent and over	2	2
	89	[1] 73		89	[1] 73

[1] 1 plant made 2 kinds of cubes using starch binder for 1 and starch and asphalt for the other; hence, the sum of these items exceeds the number of active plants.

Shipments.—Local sales (called for by passenger car or delivered by truck) account for 78 percent of the 1943 total sales; other than local (by truck to points in Wisconsin, Minnesota, Michigan, Iowa, and Illinois), 16 percent; and by rail (to points in Wisconsin, Michigan, and Minnesota), 6 percent.

Shipments of packaged fuel by method of movement, 1941–43, in net tons

Year	Shipped by truck			Shipped by rail	Total
	Local sales [1]	Other than local sales	Total truck		
1941	254,347	11,382	265,729	4,399	270,128
1942	220,063	22,203	242,266	10,944	253,210
1943	167,800	33,582	201,382	14,137	215,519

Summary	1057
Reserves	1057
Production	1057
Uses	1058
U. S. Government specifications	1059
Imports	1059
World production	1060

SUMMARY

The production of peat in the United States in 1943, according to reports received by the Bureau of Mines, totaled 60,002 short tons, valued at $491,460. The 1943 output declined from the 1942 production of 71,500 tons, valued at $516,887, and was slightly more than half the peak United States production of 107,261 short tons in 1918. As indicated on some of the reports submitted by the operators, the decline in production is due largely to cessation of operations at many peat bogs because of a labor shortage.

Since 1940, imports of peat moss have been curtailed drastically on account of the war. In 1943, imports were 59,427 short tons, valued at $1,577,388, compared with 49,236 tons in 1942, valued at $1,219,473. No exports were reported for either year; thus, the quantity available for domestic consumption in 1943 was 119,429 tons, a slight decline from the 120,736 tons available in 1942. Virtually all of the peat produced in the United States is used for soil improvement and in mixed fertilizers. None of the operators reporting to the Bureau indicated its use as fuel.

A directory of names and addresses of operators who reported 1943 production to the Bureau of Mines has been prepared and will be sent, upon request, to interested persons.

Reserves.—About half of the States contain some peat reserves, which constitute an important part of the natural resources of the country. The total calculated as air-dried peat has been estimated to be 13,827,000,000 tons.[1] Minnesota, Wisconsin, and Michigan together contain 75 percent of the reserves, and 14 percent of the country's total is in Florida; the remainder is scattered principally throughout the New England and Pacific Coast States.

PRODUCTION

Excavating, harvesting, and drying of peat require considerable labor, hence the present labor shortage is largely responsible for the decline in peat output. The 1943 production of 60,002 net tons, as reported to the Bureau of Mines by 37 producers operating in 17 States, is comparable with 71,500 tons produced in 1942 by 41 operators in 17 States.

---

[1] Soper, E. K., and Osbon, C. C., The Occurrence and Uses of Peat in the United States: Geol. Survey Bull. 728, 1922, p. 92.

The average value a ton in 1943 was $8.19, an increase of 13.3 percent over the 1942 value of $7.23. Production and value for the years 1938–43 are shown in the following table:

Peat produced in the United States, 1938–43

Year	Short tons	Value	Year	Short tons	Value
1938	45,933	$286,127	1941	86,503	$657,556
1939	55,483	362,066	1942	71,500	516,887
1940	70,097	516,865	1943	60,002	491,460

Figure 1 illustrates graphically the trend in production and value of peat from 1908 to 1926 and 1934 to 1943. No data are available for 1927 to 1933, inclusive, as the Federal Government made no canvass of the peat industry for those years.

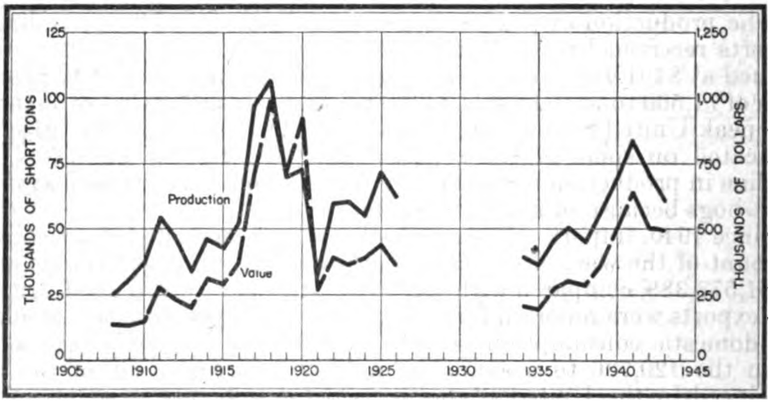

FIGURE 1.—Quantity and value of peat production, 1908–43; no data available for 1927–33.

In 1943, the producing States, in order of output, were Illinois, New Jersey, New York, Pennsylvania, Michigan, Minnesota, California, Iowa, Florida, Maine, Wisconsin, Georgia, Ohio, Texas, Massachusetts, New Hampshire, and Washington. In 1942, Illinois led in output and was followed by New York, Michigan, and New Jersey; the order of the other States also varied from that in 1943.

Peat humus comprised 45 percent of the total production, reed or sedge peat 36 percent, and moss peat 19 percent. Peat humus was produced in 9 States, reed or sedge peat in 9, and moss peat in 7.

USES

In 1943, as for many years past, a large percentage of the peat sold in the United States was used for soil improvement. In 1943, the operators reported 66 percent used for this purpose, 27 percent in mixed fertilizers, and 7 percent for other uses, including litter for barns and poultry yards. Peat is utilized also as packing for fruits, vegetables, shrubs, and fragile articles. As in previous years, no sales of peat for fuel purposes were reported. In some European countries, peat is used extensively as fuel; but, except for regional emergencies, it has not been used for this purpose on a commercial scale in this country because the supply of higher-grade fuels has been plentiful.

During the World War of 1914–18, moss peat was collected for surgical dressings, and 595,540 [2] moss-peat pads were prepared in this country and used in military hospitals both here and in Europe. Most of the moss peat was from Maine, Washington, and Oregon, and the pads were prepared under the direction of the American Red Cross. During the present war, none have been made from peat because of a shortage of trained personnel and the plentiful supply of cotton together with facilities for making surgical dressings therefrom.

United States Government specifications.—In purchasing peat, the Federal Government requires certain specifications to be met. These may be obtained from the Procurement Division, United States Treasury Department, Washington, D. C.

IMPORTS

Before 1940, Germany was the principal exporter of peat to the United States. In 1939, imports from Germany were 28,127 short tons valued at $389,597; the Netherlands and Sweden together exported 35,071 tons to the United States in the same year. In 1943, imports totaled 59,427 short tons valued at $1,577,388, all of which came from Canada. The decline in imports from other countries presented United States producers with an opportunity to increase their output of peat moss; however, the general labor shortage has prevented operators from taking full advantage of the situation.

The average value of imported peat in 1943 was $26.54, compared with $24.77 in 1942.

Peat moss imported for consumption in the United States, 1938–43

Year	Short tons	Value	Year	Short tons	Value
1938	69,509	$1,092,942	1941	30,342	$704,264
1939	78,611	1,204,883	1942	49,236	1,219,473
1940	21,689	454,632	1943	59,427	1,577,388

WORLD PRODUCTION

Unsettled conditions throughout the world have made it difficult to obtain data on the production of peat in foreign countries. The latest available data are given in the following table:

World production of peat, 1939–43, by countries [1]

[Compiled by B. B. Waldbauer]

Country [1]	1939	1940	1941	1942	1943

GENERAL REVIEW

The outstanding change affecting the supply and demand for all oils in 1943 was the progressive improvement in the transportation situation, with the completion of new pipe lines, the expansion of the tank-car movements of crude oil and products, and an advance in tanker movements as the submarine menace was brought under control. The increased number of tankers available facilitated the shipment of domestic oil to our Allies and our expeditionary forces. The opening of the Mediterranean route made the long haul around Africa unnecessary and the shipment of larger quantities of oil from Caribbean and Persian Gulf sources possible.

The demand for all oils in the United States totaled 1,670 million barrels in 1943—an all-time record and a gain of 103 million barrels or almost 7 percent compared with 1942. The primary factor in increased demand was the rapid rise in war requirements that materialized after the first quarter of 1943. These requirements proved to be much greater than had been anticipated. The tremendous increase in the program for aviation-gasoline production was a major factor in arresting the downward trend of total motor-fuel demand. Large increments in fuel-oil supply were needed for expanding shipping and naval uses. Considering the rate of demand at the end of 1943, a much larger increase may be expected in total oil demand in 1944 than in 1943.

---

[1] Data for 1943 are preliminary; detailed statistics with final revisions will be released later.

The world production of crude petroleum is estimated at about 2,222 million barrels in 1943 compared with 2,071 million in 1942—a gain of about 7 percent. The principal increases were 117 million barrels for the United States, 30 million for Venezuela, 12 million for Iraq, and possibly 11 million for the Netherlands Indies. Further substantial gains may be expected in 1944 for the United States, Venezuela, Colombia, and the Persian Gulf area.

Total demand for all oils in the United States, 1934–43

[Millions of barrels]

Year	Domestic demand	Exports	Total demand	Year	Domestic demand	Exports	Total demand
1934	920.2	114.5	1,034.7	1939	1,231.1	188.9	1,420.0
1935	983.7	129.0	1,112.7	1940	1,326.6	130.5	1,457.1
1936	1,092.7	132.0	1,224.7	1941	1,485.8	108.8	1,594.6
1937	1,169.7	172.8	1,342.5	1942	1,449.9	116.9	1,566.8
1938	1,137.1	193.7	1,330.8	1943 [1]	1,520.9	148.6	1,669.5

[1] Subject to revision.

The principal changes in the domestic supply of all oils in 1943 included a gain of almost 117 million barrels in production of crude, an increase of about 5 million barrels in the output of natural gasoline and cycle plants, a rise of 27 million barrels in total imports, and a withdrawal of only about 12 million barrels from stocks compared with a reduction in stocks of over 58 million in 1942. The record production of crude petroleum totaled 1,503 million barrels. The largest gains were 110 million barrels for Texas and 36 million for California, and the chief declines were 24 million barrels for Illinois, almost 18 million for Oklahoma, and 10 million for Mississippi. Imports of all oils rose sharply after the first quarter of 1943. There was little change in the amount of crude imported, but residual fuel-oil imports increased 8 million barrels and distillate fuel-oil imports 12 million. The 12-million-barrel decline in total stocks represented an increase of 6 million in crude stocks and a drop of 18 million barrels in stocks of refined oils. Total stocks in California were reduced 27 million barrels, whereas total stocks east of California increased 15 million.

The supply of oil for use in the West Coast States and for military and naval operations in the Pacific continued to be a major problem in 1943. Owing to the shortage of available tankers it was imperative to secure as large a supply as possible from California. The production of crude petroleum was increased from 230 million barrels in 1941 to 248 million in 1942 and to over 284 million in 1943. Heavy withdrawals from stocks have supplemented the supply. About 27 million barrels were withdrawn from stocks of all oils in 1943 compared with a reduction of 12 million in 1942. The total demand for all oils of California origin has expanded from 254 million barrels in 1941 to 275 million in 1942 and to 328 million in 1943. The total demand for residual fuel oil, the largest single product, rose from 128 million barrels in 1942 to 164 million in 1943. Gasoline production of all grades, including aviation, has been increased materially, and the supply has been augmented by overland tank-car shipments.

With completion of most pipe-line construction projects in 1943 or early 1944 and improvement in the ocean shipping situation, the major problem in oil has shifted to supply of crude. As production of crude in the United States approaches the maximum rate desirable with respect to conservation, additional oil supplies to meet war needs will depend on a larger importation of crude for refining in the United States or on a larger output from foreign refineries, particularly of fuel oils, for direct import or for shipment to our Allies or our armed forces abroad.

The 103-million-barrel gain in the total demand for all oils in 1943 consisted of a decline of 2 million barrels for motor fuel, an increase of about 64 million barrels for residual fuel oil, a gain of over 26 million barrels for distillate fuel oil, an increase of 1 million for kerosine, a gain of 3 million for lubricating oils, and an increase of 11 million for all other oils.

Salient statistics of crude petroleum, refined products, and natural gasoline in the United States, 1939–43

	1939	1940	1941	1942	1943 [1]

The total demand for motor fuel fell from 695 million barrels in 1941 to 624 million in 1942 and to 622 million in 1943. The decline was due primarily to the restriction of civilian consumption by rationing to conserve gasoline, tires, and cars. War demands began to rise rapidly in 1943, stimulated by the need for more aviation gasoline. The military demand for gasoline is proving far larger than was anticipated, and the total demand for motor fuel probably will break all previous records in 1944. The yield of gasoline from crude petroleum fell from 44.2 percent in 1941 to 39.8 percent in 1942 and 37.1 percent in 1943. Stocks of finished gasoline declined about 6 million barrels during the year compared with a decline of over 15 million in 1942. Nation-wide rationing of gasoline became effective in December 1942, and civilian consumption was further curtailed by subsequent regulations. Available data, based upon State tax returns for 1943, indicate that the volume of gasoline sold for private automotive use was about one-third less than in 1941.

The total demand for residual fuel oil rose from 398 million barrels in 1941 to 418 million in 1942 and 481 million in 1943. Demand would have been much higher except for extensive conversions to coal in the East coast and rationing for heating purposes. In addition to rapidly expanding naval requirements, railroad consumption increased from 100 million barrels in 1942 to 116 million in 1943, and the quantity required for bunkering ships engaged in foreign trade more than doubled. Supply was augmented by an increase in refinery yield from 26.9 percent in 1942 to 29.2 percent in 1943, by a decline of 13 million barrels in stocks, and by an increase in imports from 18 million barrels in 1942 to almost 27 million in 1943. Demand was particularly heavy in the Pacific Coast States, where withdrawals from storage were almost 18 million barrels.

The total demand for distillate fuel oil rose from 190 million barrels in 1941 to 207 million in 1942 and to 234 million in 1943. The gain in total demand (27 million barrels in 1943) was supplied by an increase of about 15 million barrels in refinery production and by a rise of 12 million barrels in imports. Normally about 70 percent of the total domestic demand is used for space heating, but this amount was reduced to 65 percent in 1942 and underwent a further relative decline in 1943. Requirements for naval, vessel, and war industry uses have risen steadily, but consumption for heating has been restricted by rationing.

Supply and demand of all oils in the United States in 1943, by months

[1] Subject to revision.

[2] As reported to the Bureau of Mines.

[3] Department of Commerce.

The total demand for all oils increased steadily during 1941 from a daily average of 4,107,000 barrels in the first quarter to 4,591,000 barrels in the fourth. Total demand in 1942 was about 2 percent less than in 1941. The daily average (4,538,000 barrels) was the highest for the year in the first quarter; it declined to a low of 4,082,000 barrels daily in the third quarter and rose to 4,360,000 barrels daily in the last quarter. In 1943 daily average demand for all oils set a new record of 4,573,000 barrels, a gain of about 5 percent compared with 1941 and an increase of almost 7 percent compared with 1942. Demand was at a comparatively low level in the first quarter but rose sharply in later quarters.

A brief review of the major factors in the trend of oil supply and demand by quarters, beginning with the last quarter of 1942 and extending through the first quarter of 1944, will indicate the effect of the program of the war on military and civilian oil consumption.

The daily average demand for all oils in the last quarter of 1942 was 4,360,000 barrels—a decline of 5 percent compared with the last quarter of 1941. The total demand for gasoline showed a relative decrease of over 15 percent, whereas the demand for residual fuel oil increased only 2 percent and for distillate fuel oil about 8 percent above the previous year. Gasoline rationing was established upon a Nation-wide basis in December, but its effect on total demand was obscured by heavy advance stocking by consumers. Inauguration of the rationing of heating oils in the main consuming areas on October 1 reduced potential demand materially, but the effect was modified by the substantial gain in the number of installations compared with the previous year. The small gain in residual demand indicated that the large increases in naval and railroad consumption were largely offset by the cumulative effect of conversions to coal, of increased prices, or of actual inability to procure adequate supplies in some districts.

The daily average demand for all oils declined in the first quarter of 1943 to 4,135,000 barrels—9 percent less than in the first quarter of 1942. The transportation crisis in the East coast necessitated the curtailment of nonessential driving and a cut in the unit value of heating-oil coupons. The total demand for motor fuel was only 123 million barrels, the lowest quarterly figure in 5 years and a decline of almost 19 percent compared with the first quarter of 1942. Civilian consumption was reduced to a minimum, and military demands for gasoline had not yet assumed large proportions. Owing to rationing and conversions the total demand for distillate fuel oil and the total demand for residual fuel oil were substantially less than in the first quarter of 1942. Because of transportation difficulties and the lack of balance in demand among products, crude runs to stills (3,617,000 barrels daily) were at the lowest level of the year. The average production of crude petroleum was 3,858,000 barrels daily and exceeded demand, as over 7 million barrels were added to stocks of domestic crude. The first delivery of crude through the "Big Inch" line reached Norris City, Ill., on February 19.

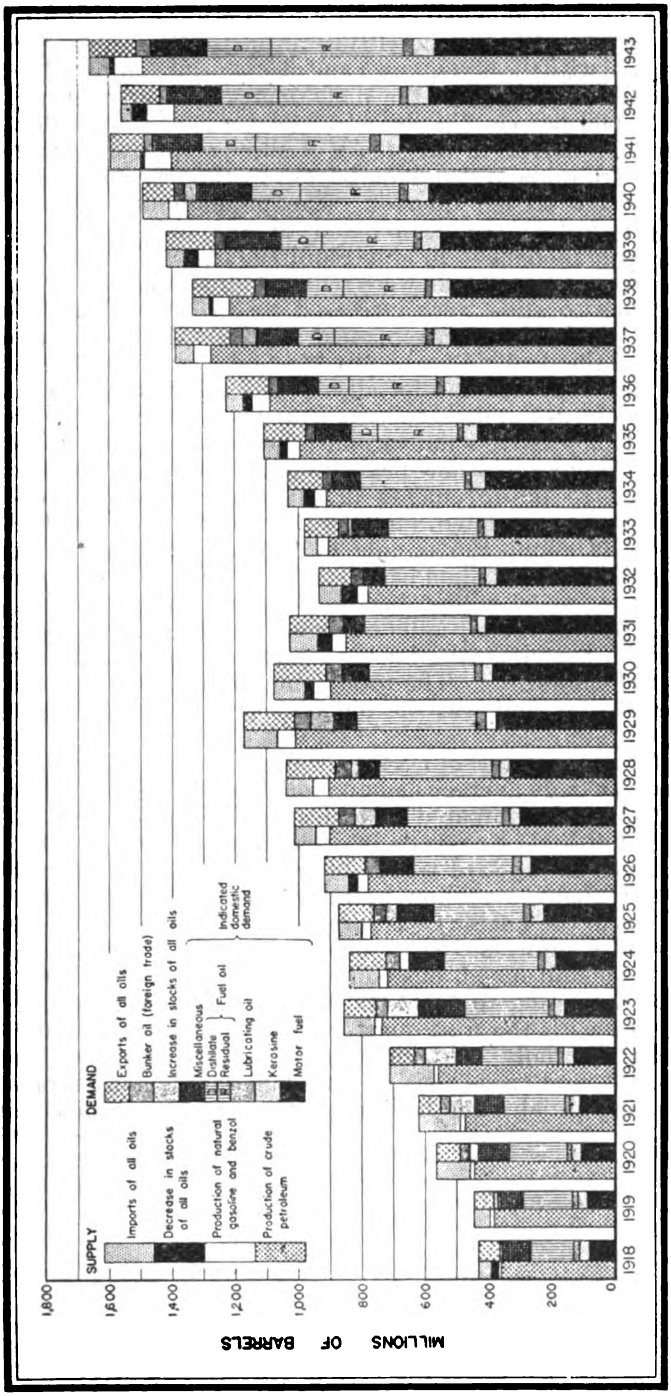

FIGURE 1.—Supply and demand of all oils in the United States, 1918–43.

The daily average demand for all oils rose abruptly to 4,564,000 barrels in the second quarter of 1943—an increase of 429,000 barrels daily, compared with the first quarter and of 9 percent compared with the second quarter of 1942. As the daily increase in crude production was only 122,000 barrels, this large demand was met by a decline of about 14 million barrels in the stocks of all oils and by an increase in total imports from about 4 million barrels in the first quarter to over 17 million in the second quarter. The predominant factor was a sudden rise in total gasoline demand to 162 million barrels that reflected a large increment in war requirements. To meet this demand, finished gasoline stocks were reduced almost 17 million barrels, and crude runs to stills were increased to 3,769,000 barrels daily. The gasoline yield, however, remained at about the low level of the first quarter as the demand for residual fuel oil was expanding rapidly.

The daily average demand for all oils was 4,750,000 barrels in the third quarter of 1943 and exceeded all previous records. Crude production (4,223,000 barrels daily) and crude runs to stills (4,062,000 barrels daily) represented new peaks in industry operations and were closely related to improvements in overland transportation. The Big Inch line was completed, and the flow of crude oil reached East Coast terminals about the middle of August. Imports of all oils amounted to almost 23 million barrels, and exports reached the highest level of the year at 50 million barrels for the quarter. Stocks of all oils declined by less than 3 million barrels, representing a decrease of over 11 million barrels in the Pacific Coast area and an increase of 8 million east of California. The total demand for motor fuel was over 171 million barrels and was the highest for any quarter since the end of 1941.

In the fourth quarter of 1943 all previous records were again exceeded, with a daily average demand for all oils of 4,841,000 barrels—a gain of 11 percent compared with the last quarter of 1942. Crude production—4,405,000 barrels daily—and crude runs—4,213,000 barrels—continued the upward trends to set new records. Stocks of all oils increased about 4 million barrels, representing a decline of 5 million barrels in the Pacific Coast States and a gain of about 9 million barrels east of California.

The total demand for all oils continued to rise in the first quarter of 1944 and amounted to 5,013,000 barrels daily—a gain of 21 percent compared with the first quarter of 1943. Crude production of 4,409,000 barrels daily was slightly above the record of the last quarter of 1943, and crude runs of 4,374,000 barrels daily represented a further substantial gain compared with any previous quarter.

The large relative gain in the first quarter was exaggerated by comparison with the abnormally low demand in the first quarter of 1943. This applied particularly to the total daily average demand for motor fuel, which increased about 32 percent. Although relative gains in subsequent quarters may be materially smaller, the total demand for all oils in 1944 promises to exceed all previous records. The completion of the new 20-inch pipe line from Texas to the East coast in March represented the last major link in the new overland transportation system.

RESERVES

Reserves of crude oil on January 1, 1944, were estimated by the American Petroleum Institute Committee on Petroleum Reserves at 20,064,152,000 barrels. These reserves include only crude oil and condensate in known and proved fields and recoverable by present production methods. Additions to reserves during 1943 totaled 1,484,786,000 barrels; but only 282,418,000 barrels represented new pools discovered during the year, and 1,202,368,000 barrels represented upward revisions of reserve estimates for fields discovered before 1943. The small decline in total reserves, amounting to about 19 million barrels during 1943, is the first that has occurred in recent years and was offset by a record production that exceeded the previous peak in 1941 by about 101 million barrels.

The failure to develop large additional reserves in the United States has stimulated interest in future sources of supply in other countries. Attention has been centered on the large potential reserves in the Persian Gulf area. The disposal of this surplus may well become the major problem in the international oil trade of the future.

The German submarine campaign was brought under control during 1943, making it possible to supplement domestic petroleum production with oil from foreign sources, and large quantities started moving into this country from the Caribbean during 1943. Steps to foster foreign supplies included the organization of the Program Division in the Petroleum Administration for War (P. A. W. Directive 70); the organization of the Petroleum Reserve Corporation; and the supplying of equipment to foreign countries for producing crude oil and the manufacturing high-octane gasoline.

The Program Division was instituted to coordinate the Petroleum Administration for War agencies on a global scale. Directive 70 was designed to bring about joint use of facilities and products in foreign operations and to operate in the interallied field to utilize tankers and other facilities to move oil over the shortest routes without cross-hauling and multiple-port loading or unloading. The Foreign Operations Committee, composed of 12 members from the industry, was charged with execution of this directive.

Estimates of proved oil reserves in the United States on January 1, 1938–44, by States [1]

[Millions of barrels]

[1] From reports of Committee on Petroleum Reserves, American Petroleum Institute, of the amount of crude oil that may be extracted by present methods from fields completely developed or sufficiently explored to permit reasonably accurate calculations. The change in reserves during any year represents total new discoveries, extensions, and revisions minus production.

The Petroleum Reserves Corporation was organized to lend Government assistance in establishing and maintaining a national policy and position in foreign oil operations. Not only is the United States the largest world user of petroleum, but it is the chief source of capital and of skilled technicians trained in the exploration for and production of petroleum. For these reasons, this country has a vital interest in foreign sources of oil that may supplement our own reserves.

Steps to assure a future supply of motor fuel independent of foreign sources included research in the liquefaction of coal and practical aspects of refining oil shale and tar sands. The Bureau of Mines has carried on extensive research and issued a number of publications regarding the liquefaction of coal.

TRANSPORTATION

The war has caused material readjustments in the world supply and distribution of oil, and these changes have necessitated a major reorganization of internal transport in the United States.

The domestic demand for all oils in the United States rose from 1,231 million barrels in 1939 to 1,486 million in 1941. During this period our exports fell from 189 million barrels to 109 million, and imports rose from 59 million barrels to 97 million. The progressive closing of European markets reduced our exports and made larger quantities of Caribbean oil available for our use. The first indication of world transport difficulties was in the spring of 1941, when some 50 tankers were temporarily withdrawn from our own use to meet war needs abroad.

After the United States entered the war in December 1941, the problem of an adequate supply of tankers became acute. The requirements of our armed forces abroad increased rapidly. Our Allies had to depend to a greater extent on oil from this country, as other sources became unavailable, and oil had to be moved by the shortest and most direct routes. The effective service of tankers was reduced by sinkings, by the delays incident to convoying, and by use for temporary storage and supply in connection with naval and new land operations.

The tanker shortage had to be met by a major diversion from the coastal service in the United States to overseas movements for war purposes. Normally the principal boat movement was from Gulf to East Coast ports and amounted to about 1,170,000 barrels daily. Elimination of the larger part of this movement and substitution of overland methods of transportation created the most acute problem in war oil supply and involved mobilization of a vast inland system of tank-car, pipe-line, barge, and truck transport.

The first step in the adjustment of transportation was reorganization of tank-car movements. In the spring of 1941 only 5,000 barrels of oil daily entered the Eastern States by tank car. By July 1942 the movement had been increased to 800,000 barrels daily and reached a peak of about 1,000,000 barrels daily in July 1943. At the height of the movement about 80,000 tank cars, out of a national total of 107,000, were used in this service. After the 24-inch crude line from Texas to the East coast was completed, tank-car deliveries declined to about 750,000 barrels daily as cars were shifted to longer routes or to other areas. In January 1943 a box-car movement of kerosine in drums was begun to the East coast and reached a peak of 25,000 barrels daily. With the withdrawal of tank cars from local distribution service, tank-truck service increased for distances up to 200 miles.

Peacetime movement of oil by barge into the Eastern States was small. Efforts to increase this movement resulted in daily shipments of 64,000 barrels by April 1942 and a further increase to 168,000 barrels daily by September 1943. The total movements via protected waterways to the Atlantic Seaboard may reach 200,000 barrels daily by the middle of 1944, but the annual average probably will not exceed 175,000 barrels daily.

The expansion of pipe-line movements to the Midwest and Eastern States was a major objective in the overland transport program. Three new projects—the Plantation, the Southeastern, and Portland-Montreal lines—were rushed to completion in 1941. A further program was inaugurated that involved the construction, reversal, or conversion of over 11,000 miles of pipe lines. Nineteen major pipe-line projects were planned by the Petroleum Administration for War to facilitate the northward and eastward flow of crude petroleum and products. The total cost of these lines was about 260 million dollars, of which about 70 percent represented Government financial assistance. Some 7,600 miles of new line were to be constructed—62 percent using new pipe and the balance using second-hand materials. In addition, the direction of flow was to be reversed in 3,300 miles of existing lines. About 90 percent of these projects was completed by November 1943, and the balance was expected to be in operation in the first half of 1944. Total pipe-line deliveries to the East coast amounted to only 42,000 barrels daily early in 1941; by November 1943 they had risen to 450,000 barrels daily and were expected to increase further to 700,000 barrels daily when all projects were finished in 1944.

The largest single pipe-line project was construction of the Big Inch 24-inch crude line from Longview, Tex., to refineries in the New York and Philadelphia districts. The line was financed by the Federal Government at a cost of about 95 million dollars and took almost a year to construct. The first delivery was made at Norris City, Ill., on February 19, 1943, and the flow through to the East coast started on August 15. The rated capacity of the line is 300,000 barrels daily. The line consists of 1,253 miles of 24-inch pipe, 111 miles of 20-inch pipe, and an extensive feeder system.

The second-largest pipe-line project was the 20-inch products line from Beaumont, Tex., to the East coast. It was Government-financed at an estimated cost of 75 million dollars and involved 1,640 miles of new construction, including feeder lines. The rated daily capacity of the line is 225,000 barrels of gasoline. Oil started moving through the southern section of the line late in December 1943, but deliveries did not reach the East coast until early in March 1944, as breaks developed when the eastern section was tested. The line is designed primarily to transport gasoline and domestic heating oils.

ADMINISTRATION AND PRORATION

The planning and administrative measures necessary to secure an adequate supply and distribution of petroleum for civilian and war purposes are under the jurisdiction of agencies appointed by the President. The principal agencies involved are the Office of Defense Transportation, the Office of Price Administration, and the Office of Petroleum Administration for War. The Petroleum Administration for War, in addition to being made a claimant agency (an agency that has the right to claim a priority on scarce material), was given the power to issue instructions and orders relating to all phases of the industry and the means for enforcing such instructions and orders.

Among the administrative orders issued in 1943 by agencies appointed by the President were the Economic Stabilizer's refusal to grant an increase in the price of crude oil; prohibition of pleasure driving in the East Coast States; lowering, by order of the Petroleum Administration for War (P. A. W.), of the octane number and volatility of motor gasoline; and extension to foreign operations of P. A. W. Directive 59, requiring joint use of facilities and products in domestic marketing. Other orders controlled the volume of gasoline produced, required the isolation of isobutanes from butane mixtures, limited the deliveries of gasoline to dealers, and established in P. A. W. district 3 a zoning plan similar to the plan in district 1. The regulation restricting hours of operation of service stations was revoked, materials restrictions were relaxed, and restrictions on high-pressure lubricants were removed.

Early in 1942 the Office of Petroleum Coordinator assumed the function of prescribing the rates of crude-oil production for the States in place of the estimates of market demand that had been issued by the Bureau of Mines theretofore. The Bureau of Mines has continued to issue the monthly forecast of motor fuel and crude-oil requirements and to supply the Petroleum Administration for War with estimates of the market demand for crude oil for the individual States. Production recommendations by the Petroleum Administration for War include consideration of reserves and of efficient production rates, as well as market demand. They cover all petroleum liquids, including condensate and natural-gas derivatives as well as crude oil.

CRUDE PETROLEUM

SUPPLY AND DEMAND

The total demand for crude petroleum was approximately 1,511 million barrels in 1943 compared with 1,411 in 1942—a gain of 100 million barrels or about 7 percent. The demand for foreign crude petroleum declined about 2 million barrels, and the demand for domestic crude petroleum rose 102 million barrels. The increase in the total demand for crude petroleum was due to the larger demand for all oils and a much smaller reduction in the stocks of refined oils in 1943 than in 1942. Compared with 1942, the production of domestic crude petroleum increased almost 117 million barrels, crude imports increased less than 2 million barrels, and total stocks of crude oil increased 6 million barrels compared with a drop of 12 million in 1942. Total crude runs to stills rose almost 96 million barrels, exports increased almost 5 million barrels, transfers gained about 5 million barrels, and other crude for fuel and losses declined 6 million barrels.

Supply of and demand for crude petroleum in the United States, 1939–43

PRODUCTION

General.—The crude-oil output of 1,503,176,000 barrels was almost 117 million barrels greater than the amount produced in 1942 and exceeded all previous records. The largest gains in 1943 were 110 million barrels for Texas and 36 million barrels for California. Substantial increases were recorded also in Kansas, Louisiana, New Mexico, and Kentucky. The principal declines were 24 million barrels for Illinois, almost 18 million barrels for Oklahoma, and 10 million barrels for Mississippi.

Texas and California retained their position as the two leading producing States, with 39.5 and 18.9 percent of the total national output. Louisiana ranked third in the list of producers, displacing Oklahoma by a very small margin. Kansas ranked fifth with 7.1

percent of the total, and Illinois dropped from fifth place in 1942 to sixth place in 1943 with 5.5 percent of the national total.

Production in the East Texas field totaled 129,112,000 barrels in 1943—a gain of about 8 million barrels compared with 1942. Production in the Coalinga field in California increased by about 12 million barrels to 31,388,000 barrels in 1943. Other Texas fields to show large gains in 1943 were Conroe, Hastings, Hawkins, and Webster. Production in the Oklahoma City field was 20,338,000 barrels in 1943—a decline of about 6 million barrels compared with 1942.

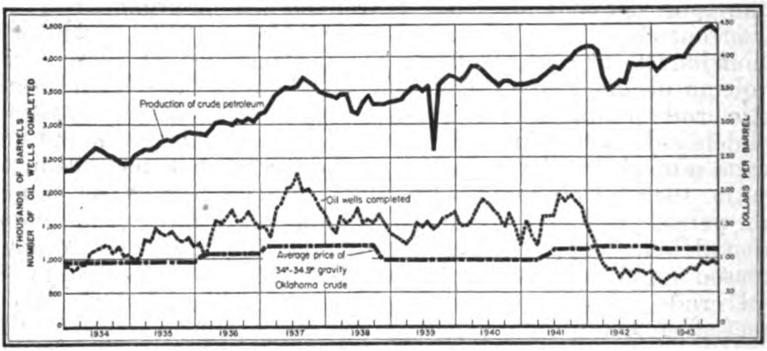

FIGURE 2.—Daily average production of crude petroleum, total number of wells completed, and average price per barrel of a selected grade of Oklahoma crude petroleum in the United States, 1934–43, by months.

[1] Oil and Gas Journal. [2] Bureau of Mines. [3] Revised.

Arkansas.—Production of petroleum was again moderately higher in 1943, gaining 4 percent over 1942 to 27,600,000 barrels. Material increases in output of the active Midway, Stevens, and Macedonia areas contrasted with small declines in almost all other fields.

Wildcat completions in 1943 almost doubled those of 1942, and six discoveries or major extensions of present fields were reported. Oil-well completions were 103 in 1942 and 137 in 1943, of which 48 were in the Stevens field (Hosston zone). The average initial production per well increased from 121 barrels in 1942 to 136 in 1943.

Dual completion of wells to permit simultaneous production from two horizons through concentric pipes has become a common practice in several Arkansas fields, with resultant savings of steel and capital investment. An interesting experiment in pressure maintenance by injection of fresh water has been started in the Midway field, Lafayette County. The operators believe that recoverable reserves of oil will be substantially increased by the procedure.

California.—In response to record demand for California oil, production increased 14 percent in 1943 over 1942 to 284,235,000 barrels, almost equaling the peak of 1929. The daily average production increased to 791,000 barrels in the last quarter and continued upward in the early months of 1944. Total output exceeded 1942 by 35,909,000 barrels of which 6,207,000 represented the gain in heavy crude to 46,923,000 barrels.

The San Joaquin Valley continued to increase its share of the State's total output, which amounted to 47 percent in 1943, with a gain of 28 million barrels. A number of fields increased their production 1 or 2 million barrels, but the largest factor was a 12-million barrel gain to 31,386,000 barrels at Coalinga, which ranked third in volume of output among fields of the United States. Midway-Sunset produced only 14,953,000 barrels in 1943, a surprising drop of over 25 percent below 1942.

In the Coastal district every important field contributed to a total increase of 6.6 million barrels (19 percent). Production of the Ventura Avenue field, which has yielded over 12 million barrels annually for many years, rose from 13,644,000 barrels in 1942 to 15,461,000 in 1943.

The Los Angeles Basin gained only 1 percent in 1943 to 110,628,000 barrels. Larger withdrawals from Dominguez, Huntington Beach, and Wilmington were almost neutralized by declines in other fields. Although Wilmington continued to be the largest producing field in California, Coalinga approached it closely in 1943 and produced more than double the output of Ventura Avenue, which ranked third, followed by Kettleman Hills and Midway-Sunset.

After a sharp decline in 1942, drilling increased rapidly in 1943 under the influence of improved oil-transportation facilities, more adequate supplies of equipment, and the urgent need for more oil. The number of oil-well completions more than doubled to total 1,150 in 1943. Of these, over 800 were in the San Joaquin Valley, 100 in the Coastal district, and 240 in the Los Angeles Basin. The most active fields were Belridge, Coalinga, Kern Front, and Midway-Sunset.

Although six new fields were discovered in the San Joaquin Valley and a number of extensions and new productive zones were opened in old fields, the total of new reserves revealed was comparatively small, far less than the total of oil produced in 1943. The most important discovery was the Pleasant Valley field about 1 mile southeast of the Coalinga Nose. The discovery well flowed 819 barrels a day from about 200 feet of Eocene sand at a depth of 9,142 feet. The field is expected to cover several hundred acres.

[3] Includes Tupman.

Colorado.—Production increased from 2,199,000 barrels in 1942 to 2,320,000 in 1943 owing to a 227,000-barrel gain at Wilson Creek, the State's most important producing field.

Ten oil-well completions were reported in 1942 and 11 in 1943, of which 8 with average initial production of 21 barrels a day were in the Rangely field and 2 with an average production of 280 barrels were at Wilson Creek. Eight dry holes were also drilled in the Rangely area. The North McCallum field was extended, and an oil discovery was reported at Clarks Lake, Larimer County, where small production was indicated from the Muddy sand.

Production of crude petroleum in Colorado, 1939–43, by fields

[4] Subject to revision.

Florida.—The first commercial oil production was found in 1943 at Sunniland, Collier County, in the southern part of Florida. The discovery well produced about 100 barrels of 20° A. P. I. gravity oil, with some water, from Lower Cretaceous beds at a depth of 11,626 feet. A widespread program of exploration and leasing in Florida and adjacent States was in progress at the end of the year.

Illinois.—Continuing its rapid decline since the peak (146,451,000 barrels) of 1940, Illinois produced 82,260,000 barrels in 1943 compared to 106,391,000 in 1942. Whereas about 90 percent of the net decline in 1942 occurred in the two major fields (Louden and Salem), only about 33 percent of the 1943 decline may be attributed to them. These fields are approaching the more stable condition of settled production, while many smaller fields are still showing rapid declines after dissipation of much of their reservoir energy in a brief period of intensive exploitation. The only important increase in production in 1943 was from the Phillipstown field, White County, which gained almost 1 million barrels over 1942. In the late months of 1943 production was relatively stable, however, as the increments from new wells offset declining output elsewhere.

Illinois ranked sixth among the States in oil production in 1943 and fifth in 1942, having been surpassed by Kansas. It supplied 5.5 percent of the total petroleum production of the United States in 1943, 7.7 percent in 1942.

Drilling was less active in 1943 than in 1942 or the boom year 1941. Oil-well completions were 1,046 with average initial daily production of 126 barrels, compared with 1,169 in 1942 with average initial of 168 barrels. The most active fields with new oil wells in each in 1943 were Mount Carmel, Wabash County, 87; Iola, Clay County, 68; Clay City, Clay and Wayne Counties, 54; and Phillipstown, White County, 50. Development centered in the southeastern counties near the Wabash River.

Twenty-eight discoveries were made, but none appeared of major importance. The largest new field was North Calvin, White County, in which 23 wells were drilled before the end of the year. Other active new fields were West Lancaster and South Covington. Over 150 extensions and new zones in older fields were reported. Of the tests drilled into older formations, one found production from Devonian limestone in the Patoka pool, Marion County; one produced from a Silurian limestone in the Mount Auburn pool, Christian County; and another in the Marine pool, Madison County. A number of unsuccessful tests of the Trenton were drilled on the west side of the Illinois Basin, inspired by the 1942 discovery of profitable Trenton production in the St. Jacob field, Madison County.

Secondary recovery by water flood was started in the Patoka pool, with encouraging prospects. This method is being used also in the Siggins pool, Cumberland County; in the Colmar-Plymouth pool, McDonough County; and in the Clay City area. Repressuring with natural gas continued in the Louden, Salem, and New Harmony fields and was extended to new areas in the Crawford County fields.

[1] Oil and Gas Journal.

Indiana.—Production declined for the second year since the 1941 peak—from 6,743,000 barrels in 1942 to 5,283,000 in 1943—because of sharply reduced output from the State's largest pool, Griffin in Gibson and Posey Counties. Although five discoveries were reported—two in Posey County, two in Spencer, and one in Gibson—none was large. The new Gibson County field—North Owensville—appeared most important, having nine wells completed with average initial daily production of 140 barrels before the end of 1943.

The reduced drilling activity centered in Posey and Gibson Counties, which had 20 and 49 oil-well completions, respectively. The Kirksville and Caborn pools were most active. Completions of oil wells in Indiana totaled 141 in 1942 and 96 in 1943, with average initial daily production of 64 barrels.

In the old Trenton area three dry holes were drilled into the Cambrian.

Kansas.—The trend of production continued upward in 1943 to 106,178,000 barrels from 97,636,000 in 1942. About half the important fields of the State increased their output, the largest gains being in the Peace Creek and Trapp-Sellens areas. The largest sources of production, in order, were: Trapp-Sellens, Silica-Raymond, and Bemis-Walters, unchanged from 1942.

Continued declines in Oklahoma and Illinois production intensified the need for Kansas oil and further stimulated the drilling effort. In 1943 oil-well completions totaled 880, with average initial daily production of 311 barrels compared with 815 in 1942 with average initial of 693 barrels. The rate of drilling increased steadily during the year, and December completions almost doubled the number in January. The most active pools, with the number of new oil wells in each, were: Carmi 64, Kraft-Prusa 60, Lindsborg 47, Chase 36, Zenith 35, and Trapp 34.

Twenty-odd new pools and numerous extensions to old ones were opened. Development pointed to significant additions to productive areas north and west of the Barton Arch group of fields and southwestward from Hutchinson. Although results of exploration in the Salina Basin have not been outstanding, a considerable number of further tests appear to be in prospect.

The most important new development was the Carmi pool, Pratt County, where about 2,500 productive acres and 15 million barrels of reserves were indicated, according to the Oil and Gas Journal. In Stafford County several new areas were discovered, and important extensions to the Drach pool were made. The Zenith pool in Stafford was linked to the Peace Creek area, Reno County, which was extended in several directions.

Greater productive possibilities of the thick Simpson sand in Pratt County were indicated by southwest extension of the Cunningham field and other drilling in the vicinity. Discovery of the Studley pool in Sheridan County, producing from the Lansing limestone, added interest to a large prospective area in the northwestern part of the State. Extensions to the Morel pool, Graham County, and the Ray pool, Phillips County, indicated that these outpost areas may contain reserves of major proportions. Drilling in the rich Russell County area linked the Greenvale and Hall-Gurney fields. After active development in 1942 the Lindsborg pool of northern McPherson County was greatly enlarged in 1943.

[1] Oil and Gas Journal.

Kentucky.—Because of the phenomenal performance of the Smith Mills field in Henderson County, production in Kentucky increased 74 percent in 1943 to 7,883,000 barrels, the greatest total since 1923. A discovery of August 1942—the Smith Mills field—produced over 3.2 million barrels in 1943 from about 80 wells.

Drilling increased materially, particularly in western Kentucky, where Henderson, Union, and Daviess Counties were most active, and resulted in 243 oil wells in 1943 in contrast to only 59 in 1942. A number of tests of the Devonian and Silurian formations were drilled in western Kentucky but with small success.

Black-oil production from the old Mariamba-Denniston and Ragland oil fields in Menifee County was revived as the war demand for fuel oils created a market. Small Weir sand production was developed on the Burkes dome, Elliott County, and is expected to cause extensive exploration in 1944 in Elliott and Jackson Counties.

[1] Subject to revision.

Louisiana.—Larger output from the Gulf Coast area raised Louisiana production to a new record of 123,592,000 barrels in 1943 compared with 115,785,000 in 1942. A dozen or more fields contributed to the gain of almost 10 million barrels in the Gulf Coast region, among them several recently discovered fields in an early stage of major development. The largest increases in production were reported from the Paradis, Gibson, Bayou Sale, and Lafitte fields.

Production in the Northern district declined from 29,310,000 barrels in 1942 to 27,398,000 in 1943. The output of the Haynesville field, the scene of an extensive drilling campaign in 1942, was over 700,000 barrels higher in 1943, and that of the Nebo and a few small fields increased moderately. Declines in other fields in 1943 were led by Olla, Rodessa, and Cotton Valley.

A general falling off of drilling activity reduced oil-well completions from 558 in 1942 to 336 in 1943. The Northern district declined sharply from 272 to 126, influenced by Haynesville operations, which resulted in 100 more wells in 1942 than in 1943. Gulf Coast completions were 286 in 1942 and 210 in 1943. The most active fields in 1943 were Caddo and Haynesville in the north, and Erath, Vinton, Pine Prairee, and Paradis in the Gulf Coast.

Three oil fields and two condensate fields were discovered in the Northern district in 1943. The Holly Ridge oil field, producing from the Tuscaloosa formation, in Tensas Parish, had three wells and six drilling at the year end and gave promise of important reserves. A large condensate reservoir was indicated by four scattered wells at Lucky, Bienville Parish, completed in the Pettit zone of the Sligo formation.

In the Gulf region nine oil and eight condensate discoveries were reported. The new oil fields that appear relatively important are Bear in Beauregard Parish; Reddell, Evangeline Parish, where production was found in the Wilcox and two sands in the Sparta formation; Napoleonville, the first oil field in Assumption Parish; and Hope Villa, East Baton Rouge Parish, which extended the trend of Miocene production. Condensate discoveries were made in the following parishes: Acadia (two), Beauregard, St. James, St. Landry, St. Martin, and Vermillion (two).

Many producing fields were enlarged by drilling, and over 30 new productive sands were opened. On the Vinton dome production was found in several different strata of the Frio formation. This development may encourage deep exploration in a number of old fields along the regional trend where similar conditions may be expected.

Louisiana became the third largest producing State in 1943, surpassing Oklahoma by a small margin. The State's oil comes from a relatively large number of fields of moderate productive capacity, rather than from a few of dominant proportions, hence no Louisiana field was among the leading 25 in the country in output in 1943. Generally conservative production practices, guided by State law, foster stability in rates of production and long life of the fields.

[4] Includes Little Creek and Summerville.

Michigan.—The reduced output of the important Reed City field, which reached a peak in 1942, was the chief cause of a decline in Michigan production from 21,754,000 barrels in 1942 to 20,768,000 in 1943. Reed City produced 38 percent of the State total despite a reduction of 1.3 million barrels compared with 1942.

Output of the active Kawkawlin field, Bay County, gained 200,000 barrels in 1943, and several of the 1942 discoveries became larger factors in production as development proceeded. Notable among these were the Fork field, Mecosta County; Evart, Osceola County, and Prosper, Missaukee County.

Oil-well completions declined from 293 in 1942 to 235 in 1943, influenced by the Reed City development, where 52 fewer wells were drilled. The most active fields were: Fork with 33 wells, Kawkawlin 32, Goodwell 18, Bangor 17, and Prosper 12.

Of six discoveries in 1943 the Goodwell field, Newago County, was the most important, though relatively small. It produced 281,000 barrels from 18 wells in the Traverse limestone. Other small Traverse fields opened in 1943 were at Woodville, Newago County; Rose Lake, Osceola County; Breedville, Van Buren County; and Fillmore, Allegan County. Dundee oil was found in the Hatton field, Clare County, where two large wells and three dry holes were drilled. One well on the southwest flank of the Rose Lake (Traverse) field was reported to have found oil in the Dundee.

Core drilling of shallow holes, a common method of determining structural conditions below the glacial drift blanket in Michigan, was more active in 1943. In the southeastern counties several tests of the hitherto unexplored Cambrian formations were planned for 1944. A second deep test of the Salina was started in the Kawkawlin field near a well that found high-pressure gas and condensate in that formation in 1942.

Production of crude petroleum in Michigan, 1939–43, by fields[1]

[Thousands of barrels]

[1] Data from Department of Conservation, Michigan.

Mississippi.—Production declined from 28,833,000 barrels in 1942 to 18,807,000 in 1943 as the Tinsley field passed its flush production peak in April 1942 and declined 50 percent in rate of output by the fourth quarter of 1943. Tinsley produced 98 percent of the State total in 1942 and 92 percent in 1943. The Vaughan-Pickens output was about 1 million barrels larger in 1943 than in 1942, and small amounts of oil were obtained from newly discovered fields.

Oil-well completions increased to 31 in 1943 compared with 20 in 1942. Active wildcatting resulted in opening four new oil fields. Two of these—Eucutta, Wayne County, and Brookhaven, Lincoln County—found oil in the Tuscaloosa formation; and Cranfield, Adams County, produced from the Wilcox. At Flora, Madison County, not far from the Tinsley field, a small well was completed in the Woodruff sand. Southwest of Natchez in Adams County oil from the Tuscaloosa was reported at a depth of 10,440 feet.

Events of early 1944 have indicated that the most important development of 1943 was the finding of oil in the Eutaw formation near the town of Heidelberg, Jasper County. The well tested deeper horizons and was not completed until after the year end, but it proved to be the discovery well of the second major oil reserve in Mississippi.

Production of crude petroleum in Mississippi, 1939–43, by months

Montana.—Lower production at Cut Bank and Kevin-Sunburst in 1943 reduced Montana production to 7,916,000 barrels from 8,074,000 in 1942. Aside from these two fields, the only major change in recent years in Montana output was in that portion of the Elk Basin field north of the Wyoming State line, where an increase of over 200,000 barrels of black oil was reported in 1943. Since 1941 the demand for Montana oil has increased materially, in particular from Canadian sources and Washington State. The Alaskan highway is expected to have an important influence on the petroleum situation in this region after the war. Wildcatting was very active in 1943, but only three small oil fields were found: Gage, Musselshell County; East Utopia, Liberty County; and Brady, Pondera County. Oil-well completions increased from 123 in 1942 to 148 in 1943, but average initial production declined from 109 barrels to 91. Cut Bank had 74 new wells averaging 127 barrels each and Kevin-Sunburst 69 wells with a 56-barrel average. The Cut Bank field was extended to the south and Kevin-Sunburst to the west and northwest.

Nebraska.—Declining output of three of the four producing fields caused a 50-percent shrinkage in Nebraska production in 1943 to 635,000 barrels, of which Falls City supplied about 67 percent and Barada 31 percent. The small Dawson production was raised by the output of six new wells. A single producer in the Falls City field completed the list of new wells in 1943.

Wildcatting was active, particularly in the central Nebraska basin, but results were disappointing, as no commercial production was found. The greatest interest was in Buffalo, Harlan, and Furnas Counties.

New Mexico.—After the cut-back in production in 1942 to 31,544,000 barrels, occasioned by war-induced transportation difficulties, the output of New Mexico recovered in 1943 to 38,411,000 barrels as more adequate facilities for moving the oil to market became available. The flow of oil increased from all important fields except Loco Hills; the largest gains were at Vacuum and Eunice. Almost 33 million barrels came from Lea County fields and 5.2 million from Eddy County. In the northwest the largest producing field is the Hospah dome, where 1943 output was about 300,000 barrels.

Drilling declined in 1943 for the second year; only 182 oil-well completions were reported—69 less than in 1942. The most active fields, in order, were: Grayburg-Jackson, Maljamar, and Square Lake, all of which were materially extended.

Four discoveries were reported. The San Simon field, Lea County, which produced from the San Andres limestone, was perhaps the most important. In Eddy County three small pools were opened as follows: Benson, producing asphaltic oil from Yates limestone at 1,830 feet; Turkey Track, producing from Queen and Greyburg at 2,700 feet; and Fenton, with production from the Delaware sand at 2,650 feet.

One well was drilled in Lea County to a depth of 9,594 feet, and two other deep tests were drilling with the hope of extending production from the Ellenburger limestone from Winkler County, Tex., into southeast New Mexico.

New York.—Production, which in 1942 attained a record of 5,421,000 barrels, under water-flood methods, declined to 5,059,000 in 1943. Although, according to the Oil Weekly, oil-well completions increased from 711 in 1942 to 781 in 1943, water-input well completions declined from 502 to 442, indicating that development of new flood acreage has slowed down.

Rising costs and a fixed price ceiling of $3.00 per barrel for Pennsylvania-Grade oil probably explain the lack of an aggressive production program.

Ohio.—The decline in production from 3,543,000 barrels in 1942 to 3,322,000 in 1943 resulted chiefly from a sharp reduction in the output of Corning-Grade oil. Operators are inclined to regard the ceiling price of $1.31 per barrel for this oil as too low to stimulate development. The production of Pennsylvania-Grade oil, however, increased from 1,637,000 barrels to 1,719,000 barrels, influenced by flush production from the Clayton pool.

Oil-well completions were 152 in 1943 compared with 235 in 1942, according to the Oil Weekly. Perry was again the most active county, with 55 oil wells completed, of which 33 were in the prolific Clayton (Clinton-sand) pool. Perhaps the largest Clinton-sand well ever drilled in Ohio was completed in Falls Township, Muskingum County, with an initial daily production of 550 barrels. Offset wells, however, were disappointing. In Blue Rock Township of the same county an Oriskany-sand oil well yielded 40 barrels initially. Several deep tests of the Clinton (below 4,500 feet) were unproductive, as was a well in Olive Township, Meigs County, that reached the Trenton limestone at a depth of 6,884 feet and was drilled to a total depth of 7,466 feet.

Oklahoma.—The decline in production that began in 1938 continued in 1943, when total output was 123,152,000 barrels, a reduction of 17.5 million barrels (12 percent) from 1942. Declines in Oklahoma City and the Seminole district, which produced 26,484,000 and 16,599,000 barrels, respectively, in 1943 totaled 10 million barrels or 57 percent of the State's total decline. Since 1937 almost half of the total decline in production has been in these two leading areas. Oklahoma was replaced by Louisiana in 1943 as the third largest producing State.

Fields showing the largest gains in output in 1943 were: Pauls Valley 1.1 million barrels, Cumberland 1.0 million, and Apache 0.6 million. Material declines were reported from the Nowata County water-flood fields, in common with other such areas in the country, and from Hewitt, Cement, Cromwell, and Fitts fields.

Oil-well completions numbered 543 in 1943, 19 more than in 1942. The most active fields were Pauls Valley (40 new oil wells), where spacing requirements were relaxed from 40 to 20 acres; Loco (38); Cumberland (26); Velma (19), stimulated by discovery of oil in the Simpson zone; Cement (16); West Edmond (11); and Wewoka (10).

Among 33 discoveries, the largest reserves were indicated at West Edmond, Oklahoma County, where 11 large wells produced from the Hunton limestone at a depth of almost 7,000 feet, and active development continued in 1944. The discovery of heavy production in the second Wilcox sand at West Moore, Cleveland County, may ultimately prove to be even more significant. These two fields are on the west flank of the great Nemaha granite ridge and have caused intensive investigation over a wide area. Relatively important discoveries were made at Big Bend, Osage County (Layton-sand production); West Burnett, Pottawatomie County (Second Wilcox sand); North McLoud, Lincoln County (Wilcox sand); and Horn's Corner, Hughes County (Cromwell sand). The findings of production from the granite wash in a deep well at West Sentinal, Washita County, is expected to encourage exploration in that region to depths of over 10,000 feet.

The opening of Madrano-sand production in the Cement field added important oil reserves from which over 400,000 barrels were produced in 1943 from 13 wells. In the Cumberland field a new productive formation, the Oil Creek, adds to the potentialities of that area.

Although some water-flood operations were expanded in the Rogers, Nowata, and Wagoner Counties district, no new projects of thsi character were reported.

[1] Oil and Gas Journal.

Pennsylvania.—Production fell sharply in 1943 (11 percent) to 15,757,000 barrels, and a declining daily rate persisted from mid-1942 through 1943. Almost all of the decline is attributable to the Bradford field, where operations were substantially reduced, owing in part to dissatisfaction of the operators with the static ceiling price of $3.00 per barrel for Pennsylvania-Grade oil in the face of rising costs of production by secondary recovery methods. The decline in stocks of oil of Pennsylvania origin during the year from 1,655,000 barrels to the critically low level of 1,364,000 was accompanied by curtailment in deliveries below contract requirements.

Oil-well completions declined from 1,802 in 1942 to 1,122 in 1943 and water-input wells from 1,620 to 1,104 according to the Oil Weekly. Only two small discoveries were reported—one in German Township, Fayette County (Speechley sand), and one in Cumberland Township, Greene County (Dunkard sand).

The experimental shaft near Franklin was completed in 1943, and two horizontal bores were drilled from it through the oil sand. No information is available on the economic aspects of the venture, which has attracted wide interest.

[1] Subject to revision.

Texas.—The gain in production from 483,097,000 barrels in 1942 to a new high of 593,520,000 barrels in 1943 represented 95 percent of the total increase in United States production. Texas produced 34.8 percent of our total domestic supply of petroleum in 1942 and 39.5 percent in 1943. The Gulf coast became the largest producing district in 1943, owing to an outstanding increase of 65.1 million barrels over 1942. All other districts raised their output, led by East Texas (19.5 million barrels) and West Texas (16.8 million).

Oil-well completions declined further in 1943 to only 2,373, or less than one-third of the 1941 total. A notable increase in the number of dry holes from 1,461 in 1942 to 1,908 in 1943, despite a general decline in drilling, was indicative of greater exploratory effort, particularly in North, Central, and South Texas. Fewer new oil wells were reported in all districts except North Texas, with greatest reductions in West and Gulf Coast Texas.

The large increase in Gulf Coast production resulted from increased well allowables rather than from new development. The leading fields, in order of production (all over 6 years old), were: Conroe, Hastings, Friendswood, Thompson, and Anahuac. Each showed an outstanding increase in 1943 output—from 4.6 to 7.8 million barrels.

The most actively developed fields were: Stowell (24 oil-well completions), Mercy (23), North La Ward (23), and West Ranch (13). Important new reserves were developed at Stowell, whose unusual situation on the upthrown side of a fault is expected to influence future exploration. Extensions or new producing sands were developed at Mercy, Mayo, Boling Dome, Humble Dome, Double Bayou, and other fields.

Among the discoveries, perhaps the most important was at North Katy in Harris-Waller Counties, where large oil reserves were indicated in Cockfield-Yegua sand about 2 miles north of the gas-condensate producing area; and at Kirby, Liberty County, where Yegua oil was found on the southwest flank of the Esperson dome. Condensate reservoirs were opened at Chesterville, Colorado County, and Jackson Pasture, Chambers County.

In South Texas wildcatting was active, particularly in the Rio Grande Valley, and a number of discoveries were reported. Promising Wilcox pools were found at Slick, Goliad County (12 wells), and at Hobson, Karnes County. Frio-sand production was discovered in the Scott-Harper field, Brooks County. The large Willamar field, Willacy County, was extended north and south.

The rate of West Texas production was about 80 percent higher in the late months of 1943 than in January, reflecting urgent demand and enlarged outlets for the oil by pipe line and rail. One major line to the Gulf coast was reopened in 1943; and two, running east and northeast, that will add over 100,000 barrels per day to capacity in 1944, were approaching completion at the end of the year.

Drilling fell sharply for the second successive year, but the great excess productive capacity developed in prior years has been adequate to meet the new demands. The most extensive development in 1943 was in the Slaughter field (255 oil wells completed), Wasson (53), Mascho (38), North Cowden (27), and Fullerton (17). Extensive additions were made to the productive areas of all of these fields.

[1] Subject to revision.
[2] Includes crude oil consumed on leases and net change in stocks held on leases for entire district.
[3] Joiner, Kilgore, Lathrop, and other pools in Cherokee, Gregg, Rusk, Smith, and Upshur Counties.
[4] Includes other fields in Falls, Freestone, Limestone, and Navarro Counties.
[5] Includes the fields in and between Wilbarger, Wichita, Clay, Montague, and Cooke Counties on the north and Runnels, Coleman, Brown, and Comanche Counties on the south.
[6] Includes crude oil consumed on leases and net change in stocks held on leases for East (exclusive of East Texas proper), Central, North, and South Texas.
[7] Carson, Gray, Hutchinson, Moore, and Wheeler Counties.
[8] Includes fields in Brooks, Duval, Hidalgo, Jim Hogg, Jim Wells, LaSalle, Live Oak, McMullen, Starr, Webb, and Zapata Counties.
[9] Includes the part of Jordan pool in Crane County.

The most significant new production was discovered in the Ellenburger (Ordovician) limestone at depths below 9,200 feet in the Kermit, Keystone, and Wheeler fields in Winkler County. Although the potentialities are great, development must be comparatively slow because of the difficulty and cost of drilling. Much exploration of deep strata from the base of the Permian down to the Ordovician is projected over a wide area. Twelve Permian discoveries were reported in seven counties; three were in Andrews, three in Pecos, and two in Howard.

Output of the East Texas district in 1943 was 13 percent higher than in 1942, owing to gains in the East Texas field (7.2 million barrels), Hawkins (8.8 million), and Van (3.0 million). The East Texas field reservoir pressure dropped only about 8.3 pounds during 1943, as it was supported by the return of about 300,000 barrels per day of salt water to the Woodbine sand. The output of 14.2 million barrels at Hawkins raised this field to thirteenth position among the leading producing fields of the country.

Although oil-well completions in 1943 (157) were below those of 1942 (239) in the East Texas district, the rate of drilling increased progressively during the year. In the most active fields—Quitman (54 new oil wells), Hawkins (33), and Kildare (28)—significant additions to proved reserves were made. Quitman and Kildare (1942 discoveries) developed into important fields in 1943.

Five oil and two condensate fields were discovered in 1943. New Hope in Franklin County is regarded as a possible major field, with production from the Rodessa and Travis Peak formations and two other productive sands indicated. The Paluxy production, found in the Manziel field, Wood County, from eight wells before the end of the year, also may attain important proportions. Other new oil fields were reported in Grayson, Hunt, and Rusk Counties. The condensate fields were at Appleby, Nacogdoches County, and Stewards Mill, Freestone County.

Production in North and Central Texas in 1943 was moderately higher than in 1942, in response to growing demand for high-gravity crude from the Mid-Continent refiners. The most active fields were: Walnut Bend (25 wells), Electra (18), K. M. A. (16), and Hildreth (13). Wildcatting resulted in a number of relatively small discoveries in formations of the Bend and Strawn series and a few in Mississippian and Ordovician (Ellenburger) rocks. Most of the discoveries were in Clay and adjacent counties; the Hildreth field in western Montague, producing from the Bend conglomerate, appeared to be the most important.

The Panhandle produced 33,295,000 barrels in 1943, an increase of 8 percent over 1942. Only 148 oil wells were completed, 110 less than in 1942 and 500 less than in 1941. The most active counties were Hutchinson (86 oil wells), Gray (47), and Carson (13).

West Virginia.—Production decreased 6 percent in 1943 to 3,349,000 barrels in the absence of stimulating influences from new discoveries or an increased price for oil. A relatively high (and rising) production cost in West Virginia is dictated by the low average rate of production per well—only about one-half barrel per day.

Oil well completions declined from 126 in 1942 to 88 in 1943, with an average initial daily production of 19 and 8 barrels per well, respectively. The most active counties, according to David B. Reger, Morgantown, W. Va., were: Wood with 15 completions, 8 of which were in the Ogdin field; Calhoun 12 completions, 9 of which were in the Sycamore field; and Clay 9.

Production of crude petroleum in West Virginia, 1939–43, by months

[1] Subject to revision.

Wyoming.—Continuing the steady increase of recent years, Wyoming produced 33,077,000 barrels in 1943, 1 percent more than in 1942. The greatest gain, at Elk Basin, reflected development of important production from the Tensleep sand, opened in December 1942. Other large gains were reported from Oregon Basin and Byron-Garland. Lance Creek, Lost Soldier, and Salt Creek declined, the last being displaced by Oregon Basin as the second largest producing field in the State.

Completion of 102 oil wells, with average initial production of 657 barrels, was reported in 1943 compared with 93 with 317 barrels in 1942. The higher per-well average in 1943 was caused by 22 wells in the new Elk Basin development, which averaged 2,147 barrels each. Oregon Basin was the most active field, with 26 new wells averaging about 300 barrels.

Two important discoveries were made—at Steamboat Butte, Fremont County, production was found in the Sundance and upper sands; and on the Gebo dome, Hot Springs County, a large well was completed in thick Embar sand. In Park County small fields producing from the Madison formation were opened at Frannie and Oregon Basin. From the standpoint of added reserves, the Elk Basin Tensleep sand exploitation overshadowed other activities, with indications of over 200 million barrels, according to early estimates. The Embar productive area at Oregon Basin also was materially enlarged.

Production of crude petroleum in Wyoming, 1939–43, by fields

WELLS

The number of wells drilled in the United States in 1943, including oil and gas wells and dry holes, continued to decline, dropping from 29,070 in 1941 to 18,151 in 1942 and to 17,884 in 1943.

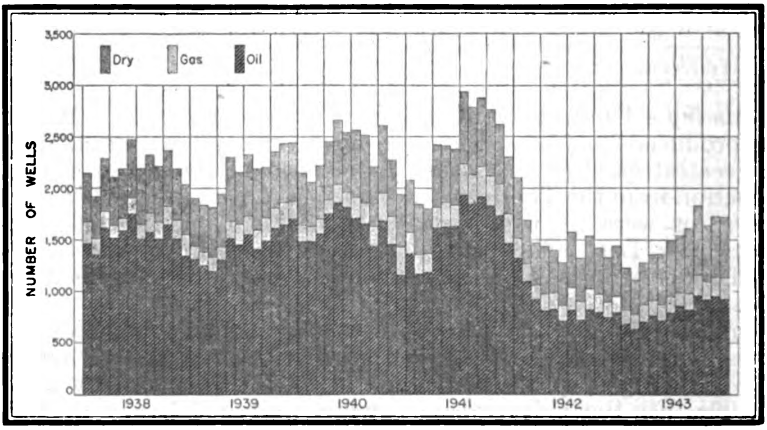

FIGURE 4.—Wells drilled in the United States, 1938-43, by months.

Oil-well completions fell from 10,524 in 1942 to 9,717 in 1943; the number of gas wells completed decreased from 2,089 in 1942 to 1,897 in 1943; and the number of dry holes rose from 5,538 in 1942 to 6,270 in 1943.

The total number of wells drilled during the first half of 1943 was substantially below the same period in 1942, but in the latter half of 1943 the relative number of wells drilled increased materially. The necessity for expanding crude production to record levels has caused much concern over the maintenance of adequate reserves and has stimulated the program to expand the drilling of exploratory wells.

The oil shortage in the Pacific Coast area resulted in an active drilling campaign in California, where the total wells drilled rose from 829 in 1942 to 1,447 in 1943. The number of oil-well completions increased by 603 over 1942. The number of wells drilled in Kentucky rose from 260 in 1942 to 656 in 1943—an increase of 396. This drilling resulted in the completion of 243 oil wells in 1943 compared with only 59 completions in 1942. Kansas ranked third among the States in the increase in the total number of wells drilled, with a gain of 216 wells. The total number of wells drilled in Texas declined from 4,688 in 1942 to 4,421 in 1943, and the number of oil-well completions decreased from 3,041 in 1942 to 2,373 in 1943. The number of wells drilled in Pennsylvania, New York, Ohio, and West Virginia decreased from 4,717 in 1942 to 4,045 in 1943, and the number of oil wells completed fell from 2,757 in 1942 to 2,194 in 1943.

STOCKS

Total crude-oil stocks increased about 6 million barrels in 1943 compared with a decline of 12 million in 1942. An increase of over 7 million barrels in the first quarter was due to transportation problems and to the relative low rate of demand for all oils, resulting from the curtailment of civilian consumption and the fact that war requirements had not begun the rapid rise that characterized later quarters of the year. During the second quarter of 1943, crude stocks declined by about 2 million barrels, but stocks of refined oils were depleted by over 11 million barrels owing primarily to the sharp rise in the military demand for gasoline. Although crude production and runs to stills increased rapidly, the supply of all oils was inadequate to meet the gain in total demand. In the third quarter, stocks of crude petroleum declined by almost 6 million barrels, in spite of a further gain in crude production and imports. With improvement in transportation facilities, the major problem became one of an adequate supply of crude petroleum from domestic sources. Every effort was made to increase crude production to record levels, and crude stocks rose by about 6 million barrels during the last quarter of 1943. Total stocks of crude petroleum amounted to 251,795,000 barrels on December 31, 1943, compared with 245,754,000 barrels on December 31, 1942. Stocks of foreign crude increased over 1 million barrels during the year, and stocks of domestic origin rose by about 5 million barrels.

Stocks of crude petroleum, natural gasoline, and refined products in the United States at end of year, 1939–1943

[1] Final figures.
[2] For comparison with succeeding years.
[3] Includes equivalents for wax, coke, and asphalt in barrels.

The data on stocks of crude oil, by States of origin, for 1943 show that the principal increases were 11.2 million barrels for Texas, 3.9 million for Illinois, 2.5 million for Louisiana, and 1.3 million for New Mexico. The largest declines in stocks by origin were 7.2 million barrels for Oklahoma, 4.2 million for all grades of California crude, and 2.4 million for Wyoming.

[2] Final figures.

CONSUMPTION AND DISTRIBUTION

Runs to stills.—Total crude runs to stills amounted to 1,430 million barrels in 1943, a gain of 96 million barrels (7.2 percent) compared with 1942. Foreign crude runs declined to 12 million barrels, the lowest level in years, but runs of domestic crude rose to a record level of 1,418 million barrels.

The principal changes in refinery operations, by districts, in 1943 were gains of 34 million barrels in crude runs in California, 33 million in the East Coast, and 28 million in the Texas Gulf Coast. The amount of crude run in California has increased steadily to meet the large demand for oil to supply the requirements of the Navy, war industries, and the railroads. Crude runs were 24 percent higher in 1943 than in 1941. Runs in the East Coast and Texas Gulf Coast districts rose with the improvement in overland transportation facilities for both crude petroleum and refined products, although they were still below the peak levels of 1941.

Distribution.—The total demand for domestic crude petroleum rose from 1,396 million barrels in 1942 to a new record of 1,498 million barrels in 1943—a gain of 102 million barrels or over 7 percent. The increased demand for crude petroleum was due primarily to the gain of 117 million barrels in crude production in 1943. The effect of the increase in the imports of refined products—from 24 million barrels in 1942 to 50 million in 1943—was offset by a reduction of only 18 million barrels in stocks of refined oils compared with the decline of 47 million barrels in such stocks in 1942.

Receipts of domestic and foreign crude petroleum at United States refineries totaled 1,328 million barrels in 1942 and 1,436 million in 1943. In 1943 receipts of foreign crude petroleum were only about 14 million barrels or less than 1 percent of the total; interstate receipts of domestic crude were 563 million barrels or 39.2 percent of the total; and intrastate receipts were 859 million barrels or 59.8 percent of the total. These percentages were virtually the same as in 1942.

Refinery receipts of crude in 1943, by methods of transportation, indicated that 82.1 percent of the total was delivered by pipe lines compared with 80.0 percent in 1942; that 10.7 percent was delivered by tank car and truck compared with 10.1 percent in 1942; and that only 7.2 percent was delivered by boat compared with 9.9 percent in 1942. These figures indicate the continuation of the abrupt decline in boat movements since 1941 and the further relative gain in overland shipments.

The major changes in the market demand for crude petroleum by States of origin (computed from production and changes in crude stocks by origin) in 1943 compared with 1942 were increases of about 121 million barrels for Texas, 38 million for California, 7 million for Kansas, 5 million for Louisiana, and 4 million for New Mexico. The largest decreases in crude demand were 37 million barrels for Illinois, 23 million for Oklahoma, 10 million for Mississippi, and 2 million for Pennsylvania. These changes indicate shifts in production trends and in accessibility to market under disturbed transportation conditions, as well as the availability of accumulated stocks.

Twelve States had a market demand in excess of 10 million barrels a year in 1943.

Runs to stills of crude petroleum in the United States in 1943, by districts and months [1]

[1] Subject to revision.

The total demand for Texas crude rose from 461 million barrels in 1942 to 582 million in 1943—a gain of over 26 percent. In 1943 about 344 million barrels of Texas crude were delivered to refineries within the State—an increase of 35 million compared with 1942. Shipments to refineries in other States amounted to 226 million barrels or 88 million more than in 1942. Deliveries to East Coast refineries rose from 76 million barrels to 138 million, and deliveries to the Illinois, Indiana, Kentucky, etc., district increased from 42 million to 63 in 1943. A new production record was established for Texas, and 11 million barrels were added to crude stocks of origin during the year.

The demand for California crude increased from 250 million barrels in 1942 to over 288 million in 1943—a gain of 15 percent. A gain of 36 million barrels in production was supplemented by a withdrawal of 4 million barrels from crude stocks. Even with this large increment in crude supply, war demands for oil products were so high as to require a reduction of 23 million barrels in the stocks of refined oils.

The demand for Oklahoma crude was reduced from 153 million barrels in 1942 to 130 million in 1943. This decrease was due primarily to a further decline in production as the liquidation of crude stocks of origin amounted to only 7 million barrels compared with almost 13 million in 1942. Deliveries to refineries within the State were reduced by about 4 million barrels to 48 million, and deliveries to refineries in other States declined 20 million barrels. Shipments to Indiana and Illinois dropped from 48 million barrels in 1942 to 35 million in 1943.

Daily average demand for domestic crude petroleum in the United States in 1943, by States of origin and by months [1]

[1] Subject to revision.

[2] Missouri, Tennessee, and Virginia.

The demand for Louisiana crude rose from 116 million barrels in 1942 to 121 million in 1943. Deliveries to refineries within the State increased substantially as markets outside the State were curtailed by transportation difficulties. Crude production exceeded demand, and several million barrels were added to stocks of origin.

The demand for Kansas crude continued to rise and amounted to about 106 million barrels in 1943—a gain of almost 8 percent. Demand closely approximated production as the increase in crude stocks of origin was small. Deliveries to refineries within the State totaled 44 million barrels and were virtually the same as in 1942. Shipments to Indiana and Illinois rose from 34 million barrels in 1942 to about 44 million in 1943.

The market demand for Illinois crude has declined each year from the peak of 1940. Demand amounted to about 78 million barrels in 1943—a loss of 37 million barrels or 32 percent compared with 1942. Production was about 24 million barrels less in 1943; but crude stocks of origin increased by about 4 million barrels during the year, whereas such stocks were reduced by 9 million barrels in 1942. Deliveries to refineries within the State fell from 34 million barrels in 1942 to 26 million in 1943.

The demand for New Mexico crude rose from 33 million barrels in 1942 to 37 million in 1943. Deliveries to refineries within the State amounted to 3 million barrels. About 25 million barrels were shipped to Texas refineries and over 7 million barrels to refineries in Illinois.

The demand for Wyoming crude increased about 1 million barrels to total less than 36 million in 1943. As there was only a minor gain in production, the increase was due primarily to a greater liquidation of stocks of origin. Deliveries of about 14 million barrels to refineries in the State were slightly less than in 1942. Shipments to adjacent States showed a small gain, and there was an increase of about 1 million barrels in deliveries to Indiana and Illinois.

The demand for Arkansas crude remained virtually stationary at about 27 million barrels in 1943. Deliveries to refineries within the State amounted to about 13 million barrels. A decline of about 1 million barrels in shipments to the Louisiana Gulf district was offset by a gain in deliveries to Ohio refineries.

The demand for Michigan crude declined to less than 21 million barrels in 1943—a loss of over 1 million. This decrease was due primarily to reduced production and resulted in smaller deliveries to refineries within the State.

The demand for Mississippi crude amounted to less than 20 million barrels in 1943—a decline of 10 million barrels compared with 1942. Shipments to the East Coast district were reduced by 8 million barrels, and deliveries to Louisiana refineries declined about 3 million barrels. A substantial gain in movements to Kentucky and Ohio was almost offset by reduced deliveries to Illinois.

The demand for Pennsylvania crude was reduced by over 2 million barrels in 1943. The total demand of 16 million barrels closely approximated production for the year.

Distribution of crude petroleum in the United States in 1943, by States[1]

PRICES AND VALUE

Efforts were made by the petroleum industry and the Petroleum Administration for War to promote a general increase in crude-oil prices. The Office of Price Administration, however, denied the requests and recommended subsidies to maintain production from stripper wells, a program for stimulating exploration by premium prices for oil from new discoveries, Government loans for drilling, and higher prices in extreme shortage areas only. An appeal was taken to the Economic Stabilizer, but he disapproved a general increase and suggested that the industry seek other means of adjusting payments so that oil from marginal wells would not be lost and that exploratory drilling should be continued. The question of price increase was carried to Congress, where a bill was passed in the House December 13 providing for a price of not less than 80 percent of parity and not more than parity. This bill would have allowed price increases of from 35 cents to 74 cents a barrel.

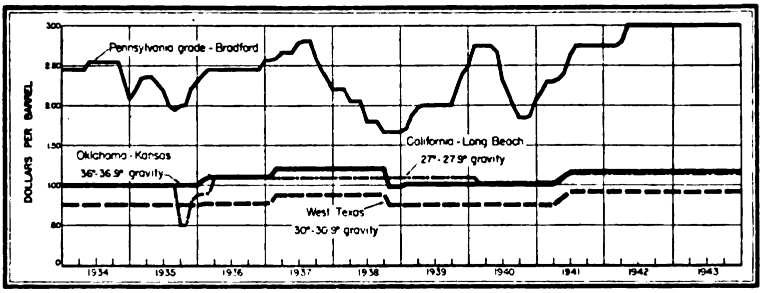

FIGURE 5.—Posted prices of selected grades of crude petroleum in the United States, 1934–43, by months.

The Office of Price Administration permitted but few increases in ceiling prices of crude oil during 1943. The principal exception was in California, where prices were increased April 1 on a graduated scale according to gravities, the maximum being an increase of 25 cents for crudes of 15° gravity and heavier. Increases under this schedule decline sharply as the gravity rises, with the effect that light oils received no increase. Prices for heavy crude oils in Wyoming likewise were increased 15 cents per barrel early in the year, and Panhandle Texas crude-oil prices advanced 7 cents. An action having the effect of a price increase in the Bradford field in Pennsylvania and New York was the reduction in the allowance for basic sediment and water from 2 percent to 1 percent.

The national average value of crude petroleum at the well will show little change in 1943 compared with the average of $1.19 per barrel in 1942. The principal gains in production were in Texas, California, Kansas, Louisiana, and New Mexico, where the value of crude is close to or below the national average. The principal decreases in production were in Illinois, with an average value of $1.36 per barrel in 1942; in Oklahoma, with an average value of $1.19 in 1942; and in Mississippi, with an average value of $0.92 in 1942.

REFINED PRODUCTS

GENERAL REVIEW

Whereas the petroleum industry in 1942 was characterized by great changes involving initiation of projects to meet the demands of war, the features of 1943 were the fruition of those projects and the emergence of an orderly program of production.

The completion of new pipe lines, the clearing of the waters near United States shores of enemy submarines, and the expansion in the tanker fleet resulted in a major improvement in the transportation of crude petroleum and products in 1943. The critical shortage in the Eastern States was relieved at the end of the first quarter, and large supplies of crude oil and products became available, in the latter half of the year, from Venezuela and other Caribbean sources. Improved distribution made possible the expansion of crude production and runs to stills to record levels in 1943.

[3] Negative quantity (overage).

It was necessary to continue and extend the measures to reduce the civilian consumption of gasoline and fuel oils in 1943. The rationing of gasoline was instituted in the Eastern States on May 15, 1942, and put on a Nation-wide basis on December 1, 1942. Pleasure driving was prohibited in the East Coast area early in 1943, and when the ban was lifted in March the basic ration was cut from 3 gallons a week to 1½ gallons but was subsequently increased to 2 gallons. The rationing of heating oils for the winter of 1942–43 was initiated on October 1, 1942, and applied to the 30 Eastern and Midwestern States. In the first quarter of 1943, when oil transportation was at the most critical stage, it became necessary to cut the coupon value for heating oils. The shortage was most acute in the New England States. The situation was improved materially in the heating season of 1943–44. Although temporary shortages occurred in some areas, the unit coupon value was maintained. Extensive conversions from fuel oil to coal had helped materially to relieve the situation in the Eastern States. However, the program to secure further conversions was discontinued when oil-transportation conditions improved and when an impending shortage of coal made it necessary to ration that fuel. Owing to the continued expansion in war demands for oil and the growing labor shortage there seems to be little prospect of more liberal allowances of either gasoline or fuel oil for civilian use in 1944.

Research has advanced technology so rapidly since the war began that new equipment and new methods have made possible the production of vital materials that heretofore had been beyond the realm of practicability. These new developments have been particularly effective in meeting the major refinery problem of supplying the enormous war demand for aviation gasoline.

The total demand for the major refined products in 1943, as compared with 1942, shows a decline of 2.0 million barrels in motor-fuel demand, a gain of 63.5 million barrels (15 percent) in residual fuel-oil demand, an increase of 26.6 million barrels (13 percent) in distillate fuel-oil demand, a gain of 1.0 million barrels (1 percent) in kerosine demand, an increase of 3.0 million barrels (8 percent) in the demand for lubricating oils, and a decline of 5.5 million barrels (12 percent) in the combined demand for asphalt and road oil. These changes in demand reflect larger imports of fuel oils and gasoline, a gain of 27 million barrels in the exports of refined products, and a decline of only 18 million barrels in the stocks of refined oils in 1943 compared with a reduction of 47 million barrels in 1942.

The relative changes in the demand for the various products resulted in a substantial shift in refinery yields. The yield of gasoline from crude oil continued to decline from 44.2 percent in 1941 to 39.8 percent in 1942 and 37.1 percent in 1943. The yield of residual fuel oil rose from 24.3 percent in 1941 to 26.9 percent in 1942 and 29.2 percent in 1943. The yield of distillate fuel oil increased from 13.4 percent in 1941 to 14.7 percent in 1942 and 14.8 percent in 1943. With the rapid rise in crude runs to stills in the latter half of 1943 and early in 1944 and the sharp upward trend in the war demands for motor fuel, the yield of gasoline began to rise and the yield of residual fuel oil to decline.

Summary of percentage yields of refined products in the United States, 1935–43

[Computed on total crude runs to stills]

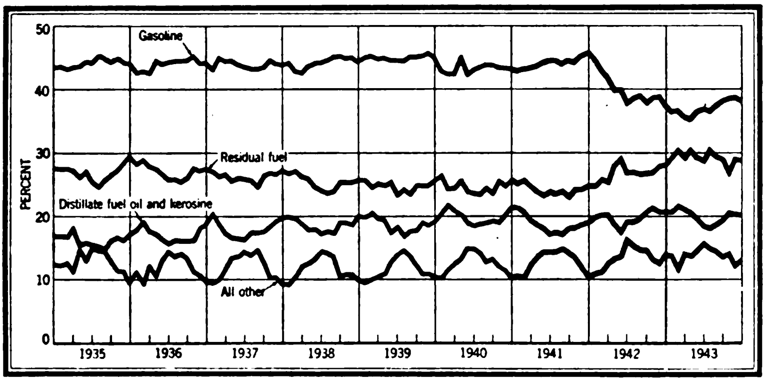

FIGURE 6.—Yields of principal products from crude oil run to stills in the United States, 1935–43, by months.

Total stocks of refined oils were reduced 47 million barrels in 1942 and were further reduced 18 million barrels in 1943. In 1942 refined stocks east of California declined 38 million barrels compared with a decrease of 9 million in the California area. In 1943 these stocks gained 5 million barrels east of California and declined 23 million barrels in California. The large reduction of stocks in 1942 reflected liquidations to meet demand during the major changes in transportation resulting from the development of overland movements to replace the Gulf-East Coast tanker shipments. The decrease in stocks in 1942 was caused primarily by the heavy demands, particularly for fuel oils, in the Pacific Coast area.

Stocks of refined products in the United States, 1942–43, by months

[Thousands of barrels, except as otherwise indicated]

[3] Subject to revision.

There were comparatively few changes in the representative prices of refined products during 1943. The price of Regular-Grade gasoline at Oklahoma refineries was 5.94 cents per gallon for the first 7 months of the year and rose to the ceiling price of 6.00 cents per gallon for the last 4 months. The tank-wagon price of kerosine at Chicago remained constant in 1943 at 10.30 cents per gallon. The price of bright stock at Oklahoma refineries, at 22.75 cents per gallon, showed no change during the year. The price of Bunker "C" fuel oil at New York was $1.37 per barrel in January, rose to a maximum of $1.80, and declined to $1.61 per barrel in December. The variations were due primarily to changes in specifications.

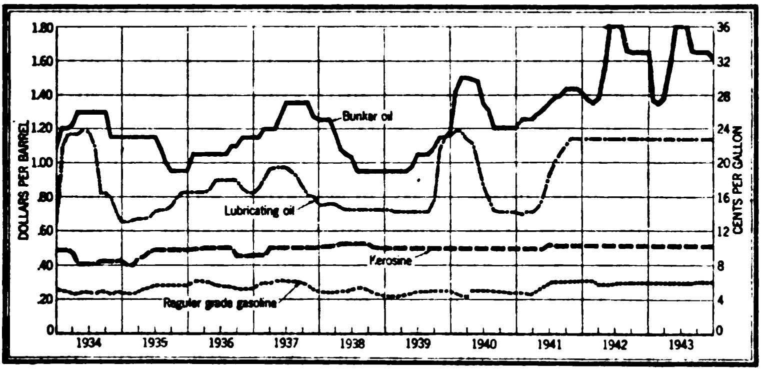

FIGURE 7.—Prices of Bunker "C" fuel oil at New York, bright stock at Oklahoma refineries, tank-wagon price of kerosine at Chicago, and Regular-Grade gasoline at refineries in Oklahoma, 1934–43, by months.

REFINING

The data from the annual survey of refinery capacity as of January 1, 1944, are not available as yet. The principal changes in crude-oil capacity were due to the operation of a larger percentage of existing capacity to meet the expansion in the volume of crude run to stills. Daily average crude run to stills rose from 3,600,000 barrels in January to a peak of 4,260,000 barrels in December. The most important developments in refinery capacity in 1943 were related to the installation of new catalytic cracking units and of equipment to produce 100-octane aviation gasoline.

Summary of refinery capacity in the United States, January 1, 1940–44

Year	Number of refineries				Capacity (barrels per day)			
	Operating	Shut down	Building	Total	Operating	Shut down	Building	Total
1940	461	86	10	557	4, 196, 694	431, 952	92, 567	4, 721, 213
1941	420	136	6	562	4, 180, 588	538, 381	141, 225	4, 860, 194
1942	430	92	1	523	4, 496, 843	459, 756	43, 400	4, 999, 999
1943	386	85	1	472	4, 404, 213	493, 098	195, 100	5, 092, 411
1944[1]								

[1] Not available.

Improvements in refining technique have developed so rapidly that plants become obsolete almost before they are put in operation. Many of these improvements particularly those that can be duplicated most easily, are still unrevealed because of military secrecy. Recent progress includes advancement in catalytic cracking, cyclization superfractionation, and desulfurization.

Whereas thermal cracking is accomplished by heat and pressure alone, catalytic cracking depends on a foreign substance known as a catalyst that modifies the chemical reaction by causing certain elements to join or to separate without the catalyst itself entering into the reaction. Thermal cracking produces a gasoline that is high in olefin content, whereas the yields of catalytic operations are high in aromatics and isoparaffins—hydrocarbons that serve excellently as base stock for aviation gasoline.

This ability to produce products of the high grade demanded by war requirements has caused a rapid development in catalytic cracking during the past 2 years. At the completion of the program some 60 plants will have catalytic cracking facilities compared with 14 in 1941. Three processes are now in operation—the Houdry, the fluid catalyst, and the Thermofor catalytic cracking. All are characterized by the problem of removing coke from the catalyst. The first plant in this country was completed in 1936 and operated with fixed catalyst cases. The first fluid catalyst was put in operation in 1942. The catalyst, in powdered form, moved with the vaporized oil during the reaction and then separated from the oil for regeneration. The Thermofor catalytic cracking (TCC) process, characterized by gravity flow of the catalyst, was put in commercial operation in 1943. The catalyst is lifted to hoppers by elevators, and the activated catalyst flows by gravity to the reaction chamber, from which it is removed by the same means after the reaction is completed. The spent catalyst is then elevated to another hopper, from which it flows by gravity through a Thermofor kiln for regeneration. The adiabatic process, announced in 1943, is an improvement on the original Houdry process, by which a greater yield of gasoline with considerably higher octane rating can be produced.

Improvement in catalysts has progressed with equipment. Early catalysts were natural or treated clays. These gave way to synthetic catalysts, and research has been developing and improving these at a rapid rate. A synthetic catalyst can be produced to emphasize the qualities desired, such as greater porosity, a greater yield of aromatics and other high-octane gasoline, longer life, and freedom from deposition of coke. The bead catalyst was among the synthetic catalysts announced in 1943. It has the advantage of great strength to resist crushing and wear, and a large yield of high-octane gasoline.

Production of aromatic hydrocarbons from naphthas by catalytic cyclization received considerable attention in 1943. The elementary aromatics are benzene, toluene, and the xylenes. Although aromatics constitute a large proportion of the yield of catalytic cracking, an even greater proportion can be obtained by hydroforming and cyclization. Whereas hydroforming converts naphthenes to aromatics by dehydrogenation, cyclization converts to aromatics.

The need for unusually pure hydrocarbons required as raw material for special products, such as toluene, butadiene, and aviation blending compounds, has necessitated much closer control in the separation of the fractions. The process has become known as superfractionation. Superfractionation originated in the natural-gasoline industry for the purpose of separating the light hydrocarbons, and the early process has been expanded to meet the more exacting requirements of present-day needs. Superfractionating equipment consists of towers equipped with bubble plates or trays by means of which the rising vapor bubbles through liquid of a temperature that varies at the different trays, each gaseous constituent condensing at that tray where the liquid in it has the same temperature as the boiling point of the fraction to be extracted. The necessity for purity in some products requires extremely precise fractionation involving the use of 150 plates or more and several towers compared with 30 to 50 plates in the older conventional process.

The utilization of high-sulfur crude oils has been a troublesome problem for refiners. The problem is to overcome the corrosive effect of sulfur compounds on processing equipment and to reduce the sulfur content in finished products to satisfactory limits. The availability of large reserves of such crude oils in West Texas, New Mexico, Wyoming, Montana, and California has led to intensive research to determine their capability of yielding desulfurized virgin distillate suitable for use as aviation base stock.

Aviation gasoline.—The production of all grades of aviation gasoline amounted to about 21 million barrels in 1941 or 3 percent of the total motor-fuel output. Production in 1943 was almost five times as great and represented about 16 percent of the total, which may increase to almost 25 percent in 1944. The continued upward revision of estimated requirements has necessitated construction of new plants and the use of short-cut methods of expanding the output of essential constituents. Even with the new plants coming into operation, it was necessary to relax the rigidity of specifications early in 1944 to obtain enough high-octane fuel. Tetraethyl lead content was increased from 4.0 cc. per gallon to 4.6 cc. January 5, 1944; distillation points also were raised to expand production.

Thirty-two of the new aviation plants were supplying 100-octane gasoline by the end of 1943, and 40 more were scheduled for completion early in 1944.

War requirements have necessitated a double octane index to describe the antiknock quality of aviation fuel—a rich-mixture (3–C) rating in addition to the lean-mixture (1–C) rating previously in use. The rich-mixture rating describes the superior quality of the fuel for take-offs, climbing, sudden loads, and similar circumstances extremely important under combat conditions and not indicated by the ordinary octane rating. The rich-mixture rating is determined in a supercharged knock-test engine by comparing the fuel to be tested with a standard reference fuel. Thus a 130 rich-mixture number indicates that the fuel is 30 percent better than the reference fuel. Specifications for the two upper grades of aviation fuel are 100/130 and 91/96.

Cumene, first produced for aviation-fuel blending in 1942, has been the principal rich-mixture additive. It was being manufactured in substantial quantities in 18 plants in 1943. Other additives about five times as potent as cumene came into use during 1943, and together made possible a surplus of rich-mixture fuel, with the result that by the end of 1943 the emphasis was on the production of lean-mixture rather than rich-mixture fuel.

Quality of gasoline.—As a result of the pressure to increase the output of aviation gasoline, the quality of normal grades began to suffer early in the war, when the octane number was reduced from 72–74 to 71–72 for Regular Grade, and from a minimum of 80 to a minimum of 78 for Premium Grade because of insufficient tetra-ethyl lead. The supply of tetra-ethyl lead, however, improved so that by October 16, 1942, the minimum of 80 octane for Premium-Grade fuel was reinstated. The Bureau of Mines Cooperative Fuel Research Motor-Gasoline Survey for the winter 1942–43 found an average of 79.6 octane for Premium-Grade gasoline and 72.5 octane for Regular-Grade, compared with 80.2 and 74.4 octane, respectively, in the winter 1940–41 survey.

The Ethyl Corporation in January 1943 permitted production of 78 minimum gasoline where production of war material prevented refiners from meeting the 80-octane specification. The Petroleum Administration for War placed a maximum as of November 1, 1943, of 72 octane on Regular-Grade gasoline and 76 octane on Premium-Grade, and the Ethyl Corporation placed a minimum of 75 octane on Premium-Grade. Thus the octane rating of Premium-Grade gasoline at the end of 1943 was but little above the 74.4-octane average found for Regular Grade in the winter 1941–42 survey. Furthermore, the volatility of the gasoline was reduced by the same instructions from the Petroleum Administration for War at the time of the year when it is usually raised. These reductions in motor-fuel quality were made not only to foster the production of aviation fuel but also to provide 80-octane fuel for all military ground vehicles in foreign zones.

MOTOR FUEL

The total demand for motor fuel reflects the combined trends of the growing requirements of our armed forces, the reduction in less essential civilian consumption, and changes in exports. The most significant factor in 1942 was the rationing of gasoline for civilian automotive use, which caused a sharp decline in total gasoline demand, disturbed the balance of refinery operations, and reduced the yield of gasoline from crude. The major trend in 1943 was the expansion in war requirements to an amount far greater than had been anticipated. Total demand and yield from crude fell to the lowest levels in the first quarter of the year and then began to rise sharply.

The total demand for motor fuel declined from 695 million barrels in 1941 to 624 million in 1942 and to 622 million in 1943. The quarterly trend of demand in 1943 compared with 1942 shows a decrease of over 27 million barrels in the first quarter, a gain of 1 million barrels in the second quarter, and increases of 10 million and 15 million barrels, respectively, in the third and fourth quarters. After the first quarter the rise in war requirements more than offset any further declines in civilian consumption. Total demand in 1944 probably will set a new record and materially exceed even the previous peak of 1941.

Exports.—Exports of gasoline, including shipments to noncontiguous Territories, were reduced to about 25 million barrels in 1940. After a small gain in 1941, they rose to 35 million barrels in 1942 and to over 51 million in 1943. Virtually all the increase in the last 3 years can be attributed to larger shipments of aviation gasoline. The adaptability of refinery equipment and the varied materials available as blending agents have made the United States the major source of 100-octane gasoline, and exports should continue to increase as military operations expand.

Domestic demand.—Statistics covering the domestic demand for motor fuel include consumption for all purposes in continental United States and all shipments consigned to our armed forces abroad. The trend of domestic demand is a resultant of the decline in civilian consumption and the increase in total military use. Without accurate data on the distribution of military consumption at home and abroad, it is very difficult to determine total consumption in continental United States, particularly by States. The distribution of total civilian consumption, however, is indicated by State data relating to the volume of taxable gasoline.

Distribution of domestic motor-fuel demand, 1925–43 [1]

[Thousands of barrels of 42 gallons]

Year	Motor-fuel demand		Busses	Passenger cars			Trucks		
	Total	Automotive		Highway	City	Total	Highway	City	Total
1925	226,329	201.433	3,391	80,653	74.285	154,938	8,466	34.638	43,104

[1] Revised.

[2] Subject to revision.

The total domestic demand for motor fuel, including shipments to our armed forces abroad, declined from 589 million barrels in 1942 to 571 million in 1943. Automotive consumption is estimated at about 475 million barrels in 1942 and 384 million in 1943. The domestic demand for motor fuel in 1942 and 1943 was more complex than in any previous period in the history of Bureau of Mines statistics. Nonhighway gasoline consumption and losses, which in recent normal years have averaged about 11 percent of the domestic demand, were swelled by our military requirements at home and abroad to 33 percent of the total in 1943.

The automotive use of gasoline was affected by variations in rationing for the various types of vehicles and for different regions. Consumption of gasoline by commercial vehicles declined only moderately, but that by passenger cars was curtailed severely by rationing. Most of the reduction in rural-highway truck traffic was in the single units. Miles traveled by combination units declined but little, resulting in fewer miles per gallon for trucks, with the consequence that gasoline consumption by trucks was reduced less than the reduction in traffic.

Gasoline consumption in the Eastern Seaboard States, already severely curtailed by rationing, underwent further restriction toward the end of 1942, when military requirements depleted stocks in that area and led to a ban on pleasure driving from January 7 to March 3. State tax statistics indicate that automotive gasoline consumption in this area dropped from 12.4 million barrels in November 1942 to 10.7 million in December 1942 and to 8.9 million in January 1943. Relaxation of the pleasure-driving ban on March 3 permitted an increase; but the ban, again instituted on May 20 in the critical shortage area, which included the Atlantic Seaboard States north of the Carolinas, kept gasoline consumption low during the summer until the cancellation of the ban on September 1, in which month consumption in this area reached its peak for the year.

The institution of rationing in the remainder of the country on December 1, 1942, caused automotive demand for motor fuel in that area to drop from 29.4 million barrels in November 1942 to 16.5 million in December 1942. Although automobile operation was reduced sharply, much of this drop in demand was caused by users accumulating stocks in anticipation of rationing, followed by a lack of buying until the surplus stocks were used. Recovery was rapid, consumption reaching a peak in July 1943.

A comprehensive survey of truck traffic, published by the Public Roads Administration in 1943, indicates that the proportion of trucks on highways has increased at a greater rate than the Bureau had estimated from toll-facility statistics. The estimated distribution of motor fuel used on rural highways has been based upon studies over a period of years by the Public Roads Administration on miles traveled, miles per gallon, and other traffic data supplemented by annual statistics gathered by the Bureau of Mines on traffic over toll and other measuring facilities. The distribution of motor fuel used on city streets has been based upon traffic surveys in the various cities, with other traffic data. The figures presented herewith have been revised in accordance with the findings in the truck survey mentioned above.

Motor-fuel consumption per motor-vehicle unit in use on July 1, 1939–43 [1]

Year	Passenger-cars			Trucks		
	Consumption (thousands of barrels)	Number of vehicles	Consumption per unit (barrels)	Consumption (thousands of barrels)	Number of vehicles	Consumption per unit (barrels)
1939	358,844	24,342,900	14.74	123,259	4,340,600	28.40
1940 [2]	376,612	25,385,900	14.84	134,434	4,531,700	29.67
1941 [2]	424,710	27,709,200	15.33	144,247	4,788,300	30.12
1942 [2]	327,962	26,946,600	12.17	129,063	4,801,400	26.88
1943 [2]	244,628	25,127,800	9.74	121,504	4,633,000	26.23

[1] Excludes gasoline consumed by busses and for nonautomotive uses.
[2] Subject to revision.

Production.—Motor-fuel output showed a small gain—from 608,900,000 barrels in 1942 to 610,533,000 in 1943. The production in 1943 comprised 216,773,000 barrels of straight-run gasoline, 314,454,000 barrels of cracked gasoline, 2,400,000 barrels of benzol, and 76,906,000 barrels of natural gasoline and cycle products. The production of cracked gasoline increased by almost 18 million barrels, the production of straight-run gasoline declined by about 17 million barrels, and the production of natural gasoline for motor fuel gained about 1 million barrels.

Yields.—The yield of gasoline from crude petroleum declined from 44.2 percent in 1941 to 39.8 percent in 1942 and 37.1 percent in 1943. This reduction in gasoline yield reflects the decline in gasoline demand due to the curtailment of civilian consumption and the early rise in fuel-oil requirements for war-plant and naval purposes. The yield of gasoline was 36.5 percent in January 1943, declined to a low of 35.3 percent in April, and had risen to 38.7 percent by November. With the continued sharp increase in military requirements, a further substantial increase in the gasoline yield may be expected in 1944. The yield of cracked gasoline declined from 22.3 percent in 1942 to 22.0 percent in 1943, and the yield of straight-run fell from 17.5 percent to 15.1 percent.

Production of gasoline in the United States in 1943, by methods of manufacture, districts, and months [1]

[1] Subject to revision.

[2] Based upon crude runs to stills.

Prices.—There were only minor changes in the representative prices for gasoline in 1943. Office of Price Administration Schedule 88, signed February 2, 1942, had provided that prices for petroleum products in effect October 1, 1941, should be ceiling prices, except at service stations.

The average group 3 refinery price for gasoline, with a ceiling price of 6.00 cents per gallon, was 5.96 cents per gallon in 1943 compared with 5.91 cents in 1942. The average remained at 5.94 cents from September 1942 through July 1943 and rose to 5.96 cents in August 1943 and to 6.00 cents in September, remaining at that level for the rest of the year.

The average 50-city dealers' net price for gasoline was 10.45 cents per gallon in 1943 compared with 10.44 cents in 1942. It gradually rose from 10.37 cents in January 1943 to 10.51 cents at the end of the year.

The average 50-city service-station price, including State and local taxes, was 18.93 cents per gallon in 1942 and 19.03 cents in 1943. This price shows wider fluctuations because of the more varied local conditions involved.

Average monthly prices of gasoline in the United States, 1942–43, in cents per gallon

[2] American Petroleum Institute: compiled by The Texas Co.

Stocks.—Stocks of finished and unfinished gasoline continued to decline in 1943. Such stocks amounted to 93.9 million barrels at the end of 1941, fell to 80.1 million at the end of 1942, and were reduced to 75.3 million barrels on December 31, 1943. Stocks of finished gasoline were reduced by 5.8 million barrels in 1943 compared with a decline of 15.4 million in 1942. The largest reductions in 1943 were in the California and Texas Gulf districts.

Gasoline stocks are computed in terms of days' supply by dividing the stocks at the end of the month by the daily average total demand (domestic demand plus exports) for the succeeding month. Upon this basis, the number of days' supply represented by finished-gasoline stocks on December 31 was 55.9 days at the end of 1942 compared with 38.0 days at the end of 1943. This decline in days' supply is due, in part, to the increasing military consumption of gasoline and the fact that stocks in the custody of the Army or Navy are not included in the published figures.

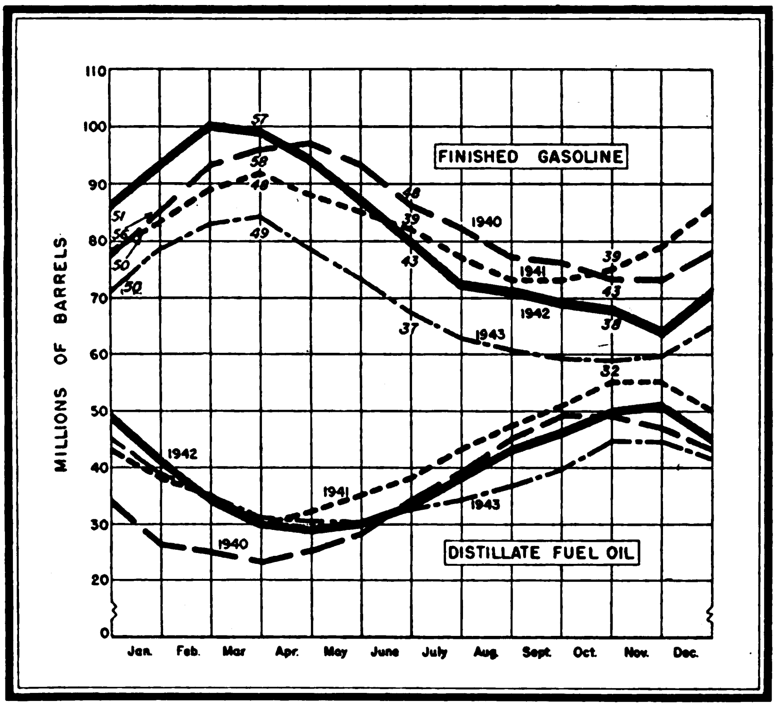

FIGURE 9.—Stocks of finished gasoline in the United States, 1940–43, by months, with figures representing days' supply at certain periods; also stocks of distillate fuel oil, 1940–43, by months.

[1] Subject to revision.

[2] Includes stocks of finished gasoline at refineries, bulk terminals, and in pipe lines.

Production and consumption by States.—The refinery production of gasoline rose from 586,971,000 barrels in 1942 to 592,425,000 barrels in 1943. Texas produced the largest amount, with 174,206,000 barrels or about 29 percent of the total in 1943. California, the second State in importance, produced 91,783,000 barrels or over 15 percent of the total. In general, production increased in the coastal States, owing to the concentration of production for war purposes, and declined in the interior States.

The lack of information on military consumption at home and abroad makes it extremely difficult to compute total consumption of gasoline by States. Such data are ordinarily compiled from the State tax records. Gasoline moving in military custody is seldom recorded by State inspection agencies. The problem is complicated further by the movement of large quantities to our armed forces abroad through the principal seaboard States.

[1] Subject to revision.

[2] American Petroleum Institute.

[3] Alabama and Mississippi included with Louisiana.

[4] Washington included with California.

[5] Maryland and South Carolina included with Georgia.

[6] Idaho and Utah included with Wyoming.

[7] Minnesota and Wisconsin included with Illinois.

[8] Missouri, Nebraska, and South Dakota included with Kansas.

[9] Tennessee included with Kentucky.

[10] Rhode Island included with Massachusetts.

Distribution.—The transportation and marketing of motor fuel have been altered radically by war conditions. The first major change resulted from the decline in the tanker movement between Gulf and East Coast ports and the expansion in overland tank-car and pipe-line shipments. Progressive restrictions on civilian consumption have reduced the volume of private automotive demand to about two-thirds normal. The rise in military requirements has been offsetting this loss, so that total demand in 1944 may exceed the former peak of 1941. This major shift from civilian to war uses has changed the whole normal system of distribution.

Motor fuel delivered by pipe lines rose from 125 million barrels in 1942 to almost 204 million in 1943. Deliveries in January 1943 amounted to about 10 million barrels and increased to 19 million barrels in December. New lines and extensions increased the movement northward from Texas and Oklahoma, the direction of flow in the lines crossing the Appalachians was reversed from west to east, and the capacity of the Plantation line was increased and new connections built to Baton Rouge, La., and Richmond, Va. The new 20-inch products line from the Gulf to the East coast was not completed until March 1944. This line will increase materially the shipments of gasoline and heating oils in 1944.

Although gasoline continues to be the major product moved, there has been a substantial increase in the shipment of other refined products by pipe line. A rough estimate for 1943 indicates that approximately 9 million barrels of kerosine and 19 million barrels of distillate fuel oil were so delivered.

Shipments of motor fuel by pipe lines in the United States in 1943, by months

Rationing.—Rationing regulations by the Office of Price Administration had an important influence on motor-fuel demand. The various types of users entitled to gasoline rations include passenger-car, motorcycle, and commercial-car operators, nonhighway users, and military forces. Passenger-car rations were of three types, indicated by A, B, and C coupons. All passenger cars except those in commercial fleets were entitled to A coupons, and B and C coupons were given for supplemental driving required in connection with individual occupation or war needs.

The most important ration regulations were:

November 22, 1942.—Value of A coupons cut from 4 to 3 gallons in the Eastern Shortage Area (17 Eastern States and the District of Columbia), except West Virginia.

December 1, 1942.—Inclusion of the remainder of the States, in addition to the Gasoline Shortage Area, in the rationing program.

December 1–2, 1942.—Nation-wide registration of dealers and intermediate distributors.

December 8, 1942.—First quota set by the Petroleum Administration for War for the Eastern Shortage Area.

December 21, 1942.—Value of A, B, and C coupons in West Virginia cut from 4 gallons to 3.

January 7, 1943.—Pleasure driving prohibited in the Eastern Shortage Area.

February 10, 1943.—West Virginia removed from shortage area, although still left in P. A. W. District I.

March 3, 1943.—Pleasure-driving ban relaxed.

March 22, 1943.—Value of A rations cut in the shortage area by extending the valid period of A coupons to 4 months, which in effect reduced the ration from 2 gallons per week to 1½.

May 20, 1943.—Ban on pleasure driving reimposed in the critical part (north of the Carolinas) of the shortage area.

May 25, 1943.—Value of T or commercial rations cut 40 percent in the critical area by extending the valid period to July 25 instead of June 30.

June 2, 1943.—Value of B and C coupons in the critical area cut from 3 to 2½ gallons.

July 15, 1943.—Use of rations authorized for vacation travel.

August 13, 1943.—Petroleum Administration for War set the first Midwest quota covering September 1943.

August 16, 1943.—Value of A, B, and C coupons in the Midwest cut from 4 to 3 gallons.

September 1, 1943.—Ban on pleasure driving in the critical part of the shortage area removed.

October 1, 1943.—Value of A rations increased to 2 gallons weekly in the Eastern Shortage Area by shortening the valid periods of currently outstanding coupons. Those previously intended to last until November 21 were changed to expire on November 8, and those valid on November 9 were assigned a valid period of 3 months instead of 4.

October 1, 1943.—Value of B and C coupons cut as follows: In the critical part of the shortage area from 2½ to 2 gallons; in the remainder of the shortage area and in the Midwest from 3 to 2 gallons.

October 11, 1943.—Petroleum Administration for War set the first quota for the Far West covering the 4th quarter of 1943.

October 12, 1943.—Value of A, B, and C coupons in the Far West cut from 4 to 3 gallons.

December 1, 1943.—New B and C ration coupons (B-2 and C-2) issued for 5 gallons each.

KEROSINE AND RANGE OIL

The domestic demand for kerosine declined slightly in 1943, as transportation difficulties and rationing in the principal consuming areas continued to be restricting factors, as they were in 1942. An increase in kerosine production in 1943 was due entirely to a corresponding gain in crude runs to stills, as the percentage yield for both 1942 and 1943 remained at the same level. Exports of kerosine under pressure of Lend-Lease needs nearly doubled in volume in 1943 compared with 1942; but imports, never an important source of supply, declined by 10 percent. Kerosine stocks continued to shrink in 1943 but to a less-pronounced degree than in 1942.

The production of kerosine increased from 67,474,000 barrels in 1942 to 72,270,000 in 1943—a gain of 7 percent. The larger output of kerosine must be attributed solely to higher runs of crude (7 percent over 1942) in 1943, as the percentage yields were the same for both years. The kerosine yield might have been even higher had not refiners endeavored to obtain maximum quantities of heavy fuel oils.

Comparative analyses of statistics for kerosine in the United States, 1942-43, by months and districts

[1] Subject to revision.

[2] Figures not available.

In the Texas Gulf Coast district, where more kerosine is made than in any other area, production increased by 27 percent in 1943 owing both to added crude runs and to a higher percentage yield. The Indiana-Illinois refinery district is the second most important source of kerosine; however, in that area the output declined by 9 percent in 1943 because of a lower percentage yield. Kerosine production dropped in the Oklahoma-Kansas and East Coast refinery districts in 1943, both important sources of this petroleum product. Lower runs of crude resulted in less kerosine for the Oklahoma-Kansas district in 1943, whereas in the East Coast a smaller percentage yield was the reason for the lower output. In other districts, such as the Appalachian, Texas Inland, Louisiana Gulf Coast, Rocky Mountain, and California, the production of kerosine increased in 1943, but a decline was reported for the Arkansas-Louisiana Inland area.

The indicated domestic demand for kerosine declined slightly from 69,767,000 barrels in 1942 to 68,731,000 in 1943, as rationing in principal consuming areas, inadequate transportation facilities, and a lower production in the East Coast (where about 65 percent of the kerosine market is located) were factors that prevented sufficient deliveries to satisfy normal requirements. The indicated demand for kerosine—as for other petroleum products—is calculated from stock fluctuations, production, imports, and exports. As data showing imports and exports for areas corresponding to refinery districts are not available, it is impossible to present a break-down of the indicated demand.

Exports of kerosine, which showed some shrinkage in 1942 due largely to tanker sinkings, developed a substantial increase in 1943 to 4,619,000 barrels, a gain of 79 percent over the 1942 total. The United Kingdom and its Dependencies continued to receive most of the kerosine exports in 1943, as they did in 1942. Kerosine shipped to Canada totaled 268,000 barrels in 1943 compared with 236,000 in 1942, and the quantity credited to the United Kingdom more than doubled, increasing from 1,671,000 barrels in 1942 to 3,782,000 in 1943.

Kerosine imports, never an important factor in the domestic supply, declined slightly from 418,000 barrels in 1942 to 375,000 in 1943.

Stocks of kerosine continued to decline in 1943, the year-end total of 9,359,000 barrels being 7 percent below the 1942 final inventory of 10,064,000 barrels. Information regarding stocks of kerosine held at bulk terminals did not become available until 1942. The break-down for kerosine storage for 1942 and 1943 was as follows: Held at refineries, 1942, 7,537,000 barrels, and 1943, 5,472,000; reported at bulk terminals, 1942, 2,527,000 barrels, and 1943, 3,887,000 barrels. Furthermore, total kerosine reported in storage represented 61 days in 1941, dropping to 40 days' supply in 1942 and to only 38 days' supply in 1943 at the respective rates of demand for the several years.

The net change in kerosine stocks for the several refinery districts in 1943 differed somewhat from those indicated for 1942. In 1942 transportation difficulties resulting from a forced change-over from water to land routes for kerosine as well as for other petroleum products caused a drastic drop in kerosine stocks on the East Coast and a decline to a smaller degree in the Indiana-Illinois refinery district, both areas of high kerosine consumption, and a rise in inventory in the Louisiana Gulf, as the product of refineries there could not be moved by the usual tanker route. In 1943 the land transportation of petroleum products (by tank car) had become better organized, with the result that a small but desirable build-up of kerosine stocks on the East coast was accomplished—the inventory rising from 2,853,000 barrels in 1942 to 3,062,000 at the end of 1943—and storage in the Indiana-Illinois refinery district also increased from 1,554,000 barrels in 1942 to 2,314,000 in 1943. Kerosine stocks in the Texas Gulf and Louisiana Gulf, important producing areas, declined in 1943, marking a more normal movement to East Coast and export markets. There was a nominal increase in kerosine stocks in the Oklahoma-Kansas refinery district (656,000 barrels in 1943 compared with 576,000 in 1942) although production declined in that area in 1943. The stock gain there could be attributed in part to a movement inland of Texas kerosine. A continued expansion of kerosine production in California in 1943, along with a curtailed export market, resulted in a 25-percent gain (525,000 barrels in 1942 and 658,000 in 1943) in quantities held in storage at the year end.

[1] Figures for 1943 by States not yet available.

The Bureau makes an annual survey of kerosine distribution by States and principal uses. The distribution for 1943 is not available at this time; however, in 1942 kerosine sales of 68,690,000 barrels varied little from the 1941 total of 68,996,000 barrels. Rationing in important consuming areas and transportation difficulties caused some shifts in principal uses. The demand for range oil declined from 41,661,000 barrels in 1941 to 39,945,000 in 1942 or from 60 percent of kerosine deliveries in 1941 to 58 percent in 1942, as adequate supplies of kerosine could not be shipped from the Gulf Coast to the North Atlantic area, an important range-oil market. Supplies tended to "back up" in the south central and adjacent territory, with the result that kerosine sales for tractor fuel and other uses expanded. Kerosine delivered for tractor fuel increased by 15 percent from 4,467,000 barrels in 1941 to 5,137,000 in 1942, but all other uses (23,608,000 barrels) were about 3 percent over the 1941 total of 22,868,000 barrels. As No. 1 fuel oil differs so little from lower grades of kerosine it is sometimes sold as range oil. This No. 1 fuel oil (4,978,000 barrels in 1942 compared with 4,449,000 in 1941) must be added to the kerosine sold as range oil to determine total range-oil requirements—44,923,000 barrels in 1942, a quantity 3 percent below the 1941 total of 46,110,000 barrels.

There were few changes in representative kerosine prices in 1943. The average monthly quotation of 4.44 cents a gallon for 41°–43° gravity water-white kerosine at refineries in Oklahoma dating from March 4, 1942, remained unchanged until September 9, 1943, when the price dropped to 4.38 cents—lowering the average for the year to 4.42 cents compared with 4.46 cents a gallon average in 1942. The tank-wagon price of kerosine at Chicago of 10.6 cents a gallon, effective December 31, 1942, held unchanged throughout 1943.

FUEL OIL

The demand for fuel oil expanded to a record volume in 1943, as the United States completed its change to a war economy. New production, imports, and transfers from crude petroleum did not satisfy market requirements, so a critical draft on stocks was necessary for the second consecutive year. The domestic demand for fuel oil increased by 14 percent from 591,358,000 barrels in 1942 to 673,428,000 in 1943, and this gain was realized in spite of rationing in some important consuming areas and the difficulties of free movement of supplies. The domestic market for both light and heavy fuel oils expanded substantially in 1943. Requirements for distillate grades increased from 185,661,000 barrels in 1942 to 208,935,000 in 1943—a gain of 13 percent—and deliveries of residual fuel oils of 464,493,000 barrels in 1943 were 14 percent above the 1942 total of 405,697,000 barrels.

The domestic demand for both light and heavy fuel oils was lower in the first quarter of 1943 compared with the same period of 1942, although the weather was colder in the 1943 quarter and industrial activities were at a higher level due to war needs. Requirements for distillate fuel oils declined by 6 percent from 65,314,000 barrels in the opening quarter of 1942 to 61,171,000 in the corresponding months of 1943, and the market for heavy grades dropped 3 percent from 108,518,000 barrels in the January–March period of 1942 to 105,103,000 in the first quarter of 1943. The shrinkage in fuel-oil requirements during the first 3 months of 1943, when reviewed from another angle, shows that the quarter's total represented only 29 percent of the year's demand for distillate grades compared with a 35-percent proportion in the first quarter of 1942; and the heavy grades marketed in the opening quarter of 1943 were 23 percent of the year's requirements compared with a 27-percent share falling within the first 3 months of 1942. Rationing of heating oils, conversions to other fuels, restrictions on oil-burner installations, and transportation difficulties were all factors that reacted negatively on the fuel-oil market during the first quarter of 1943.

[2] Interstate Commerce Commission; total includes Diesel fuel.
[3] Federal Power Commission.
[4] Figures not available.

The decline in fuel-oil demand during the opening months of 1943 was only temporary, as the trend turned sharply upward in the second quarter when deliveries of distillate grades increased by 27 percent (46,534,000 barrels for the second quarter of 1943 compared with 36,595,000 in the same period of 1942), and requirements for residual fuel oil (112,189,000 barrels) were 15 percent above the total of 97,701,000 reported in the second quarter of 1942. Sales of fuel oil increased in volume during the July–September period of 1943, when light fuel deliveries (44,935,000 barrels in the third quarter of 1943 compared with 31,975,000 in the corresponding portion of 1942) were 41 percent above the 1942 total and the market for heavy grades increased by 29 percent (118,291,000 barrels for the third quarter of 1943 compared with 91,777,000 in 1942). This pyramiding of fuel-oil deliveries falling within the third quarter of 1943 was due to several factors, namely, improved transportation facilities, stocking of supplies by dealers in anticipation of the approaching heating-oil season, and peak industrial activities in connection with the war. The percentage rate of increase in the fuel-oil demand slackened somewhat in the fourth quarter of 1943, especially for distillate grades, as consumers of heating oils were fairly well stocked from the previous quarter; furthermore December 1943 was warmer than the same month of 1942. Deliveries of light fuel oils in the final quarter of 1943 (56,295,000 barrels) were 9 percent above the demand of 51,777,000 barrels in the same period of 1942, but requirements for heavy grades (128,910,000 barrels) were 20 percent over the comparative total of 107,701,000 barrels in 1942.

There is very little available information at present regarding the change in principal demands for fuel oil in 1943 compared with 1942. However, it is known from monthly data compiled by Government agencies that the quantity of fuel oil used by the transportation industries—railroads and vessels—increased sharply in 1943. The demand for fuel oil by the Navy also expanded outstandingly because of greatly increased war activities and the addition of numerous new units to the fleet. It is believed that the remaining major demands for fuel oil in 1943 were only moderately above the 1942 levels.

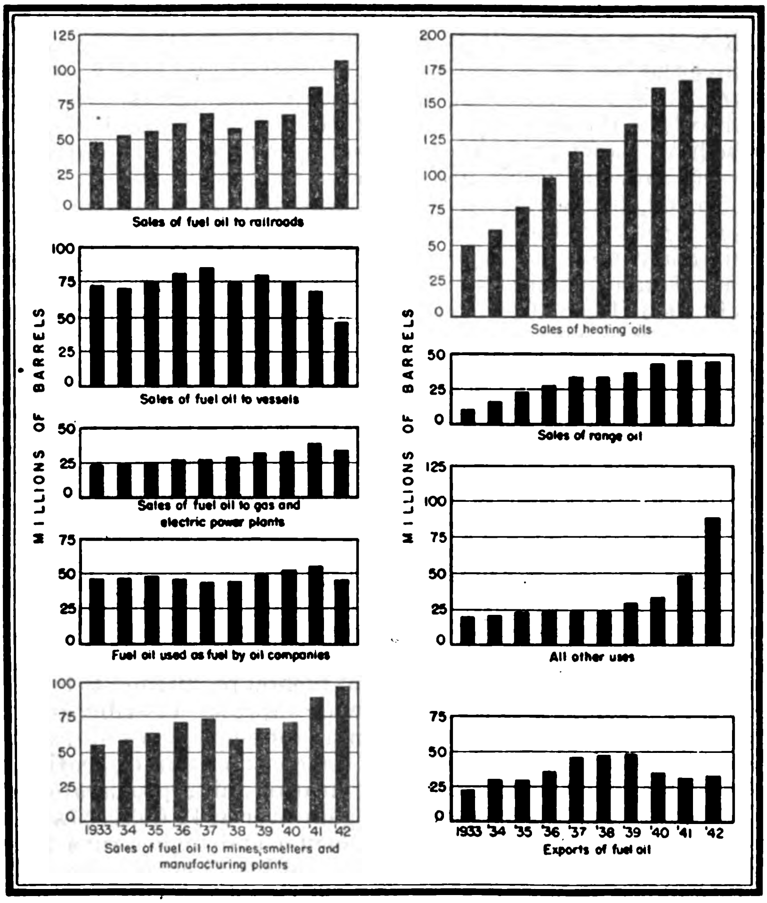

FIGURE 10.—Sales of fuel oil and range oil in the United States, 1933–42, by uses.

Class I railroads purchased 121,070,000 barrels of fuel oil in 1943, a 16-percent gain over the 1942 total of 104,072,000 barrels, according to monthly reports released by the Interstate Commerce Commission. The railroad demand for fuel oil in 1943 showed a lower percentage rate of expansion than that recorded in 1942 over 1941 (24 percent), a fact indicating that the railroad industry has probably reached peak requirements for fuel oil under prevailing war conditions.

The market for fuel-oil bunkers, at a very low level in 1942 due to sinkings by submarines, rebounded sharply in 1943, as indicated by monthly figures covering loadings on vessels engaged in foreign trade as compiled by the Division of Foreign Trade Statistics, Bureau of the Census. Vessels plying in foreign trade purchased 49,453,000 barrels of bunker fuel oil at American continental ports in 1943—a 95 percent gain over the 1942 total of 25,418,000 barrels. No records are available covering fuel-oil requirements of vessels in coastwise trade; however, it is believed that, with enemy submarines driven from coastal waters, the coastwise share of the fuel-oil bunker business will likewise have shown great improvement in 1943, so that total loadings for vessels both in foreign and coastwise trade will have expanded to about 75,000,000 barrels—a total comparable with normal requirements in recent pre-war years.

Preliminary monthly reports of the Federal Power Commission show an 18-percent increase in the use of fuel oil by electric power plants in 1943 (18,085,000 barrels in 1943 compared with 15,281,000 in 1942) in contrast with a 25-percent drop in 1942 compared with 1941 requirements. A gain in the use of fuel oil by the manufactured-gas industry in 1942 probably was repeated in 1943, so that purchases of fuel oil by the public-utility gas and electric-power plants will total about 38,000,000 barrels in 1943 compared with 33,805,000 in 1942—a 12-percent gain.

It is not believed that fuel oil going to smelters, mines, and manufacturing establishments exceeded 98,000,000 barrels in 1943 (1 percent over 1942 purchases), as forced conversion to other fuels approached peak levels and limited supplies of fuel oil in the East Coast area, where over half of the demand is located, were factors that prevented any great rise in consumption. More than 60 percent of distillate fuel oil and over one-quarter of the residual fuel oil marketed are sold for space heating; and, as total fuel-oil requirements increased 14 percent in 1943, it is evident that with improved distribution and a more generous allowance under rationing for some types of dwellings, there was at least a moderate rise in the consumption of heating oils. It is estimated that the demand for heating oil approximated 179,000,000 barrels in 1943—a 6-percent gain over 1942 deliveries.

Increased production of crude petroleum and higher runs to stills indicate some increase in the use of fuel oil by oil companies in 1943. This demand is estimated at 47,250,000 barrels for 1943—a gain of about 3 percent. Fuel oil sold for all other uses, including the Navy, probably increased by 23 percent in 1943—to about 108,000,000 barrels.

The principal uses of fuel oil are shown graphically for 1933 through 1942 in figure 10. The length of the respective columns, indicating the demand by principal uses for each year, is based upon totals reported in the annual fuel-oil survey of the Bureau. Distillate fuel oil, residual fuel oil, and kerosine sold as range oil are included.

[1] Includes Navy grade and crude oil burned as fuel.
[2] Figures for 1943 not yet available.

Important quantities of fuel oil shipped to allied countries under Lend-Lease agreements boosted the export demand from 33,670,000 barrels in 1942 to 41,628,000 in 1943—a gain of 24 percent. Distillate grades of fuel oil continued to represent the bulk of fuel-oil exports in 1943, as they have for a number of years, and totaled 24,862,000 barrels in 1943—a gain of 15 percent (28 percent increase in 1942 over 1941) compared with 21,575,000 reported for 1942. The export total for heavy fuel oil was 16,766,000 barrels in 1943—a 39-percent gain over the 1942 overseas demand of 12,095,000 barrels. The increase for residual grades in 1943, reflecting an improvement in tanker facilities and expanded war demands, is in contrast to a 14-percent decline in 1942.

The United Kingdom and Dominions of the British Commonwealth received the bulk of American exports of fuel oil for both 1942 and 1943. Light fuel oils credited to the United Kingdom increased from 15,117,000 barrels in 1942 to 16,797,000 in 1943. Larger shipments of American distillate fuel oil to Oceania (mostly to Australia and New Zealand) of 4,677,000 barrels in 1943 compared with 1,918,000 in 1942 resulted partly from the cutting off of normal supplies from the Netherlands East Indies to that area. Exports of light fuel oil to Canada dropped from 493,000 barrels in 1942 to 423,000 in 1943. A sizable item covering distillate fuel oil shipped to U. S. S. R. appears for the first time—264,000 barrels in 1943 compared with 71,000 in 1942.

Over three-fifths of all exports of residual fuel oil went to the United Kingdom in 1943 compared with about one-quarter of the 1942 total. The quantity credited to the United Kingdom increased from 3,179,000 barrels in 1942 to 10,683,000 in 1943, an expanded total made possible by a greater tanker fleet and the fading submarine menace. Relatively less important quantities of heavy fuel oil were shipped to Canada (907,000 barrels in 1943 and 1,271,000 in 1942), Mexico (584,000 barrels in 1943 and 433,000 in 1942), the West Indies (684,000 barrels in 1943 and 1,141,000 in 1942), and Oceania (456,000 barrels in 1943 and 509,000 in 1942).

The production of fuel oil increased 13 percent in 1943 compared with 1942 because of higher runs of crude to stills (7 percent over 1942) and a greater percentage yield. The output of fuel oil in 1943 (628,822,000 barrels) represents a yield of 44 percent and compares with a production of 555,615,000 barrels in 1942—a yield of 41.6 percent. When light and heavy fuel oils are reviewed separately, it is found that the production of distillate grades increased 8 percent—from 196,714,000 barrels in 1942 to 211,516,000 in 1943. As the yield for distillate fuel oil for 1943 (14.8 percent) was practically unchanged from the 1942 level (14.7 percent), increased runs of crude must be considered the sole factor resulting in the higher output. The larger share of the expanded production of fuel oils must be credited to the heavier grades, the yield of which increased 16 percent (from 358,901,000 barrels in 1942 to 417,306,000 in 1943)—a gain attributable not only to the greater volume of crude runs but to an improved yield of 29.2 percent in 1943 compared with 26.9 percent in 1942. The expanded output of heavy fuel oil was possible and most opportune at the time of a rising demand, as the 1943 market for motor fuel was below the 1942 level for the first three quarters of the year owing to inadequate transportation and to rationing. In other words, there was no need to keep down the yield of residual fuel oils to make more profitable motor fuels, the usual practice under normal conditions.

---

[1] Includes distillate fuel oil, residual fuel oil, and some crude oil burned as fuel.
[2] Figures for 1943 not yet available.

The higher production of distillate fuel oil in 1943 must be credited almost entirely to four refinery districts—the East Coast, Texas Inland, Texas Gulf Coast, and California—as in the other areas there was a decline or only a nominal gain in output of light fuel oils. The urgent need for a greater supply of light heating oils in the important East Coast consuming area in 1943 was partly met by a 22-percent expansion in production. The improved light-fuel-oil output in the East Coast district was associated mostly with a 21-percent increase in crude runs, as the yield for distillates remained fairly constant for 1942 and 1943. A 7-percent increase in crude runs to stills as well as a higher yield (6.4 percent in 1943 compared with 5.4 percent in 1942) made possible a 28-percent gain in distillate production in the Texas Inland district. Refineries operating in the Texas Gulf Coast dropped their yield of distillates from 19.8 percent in 1942 to 19.3 percent in 1943; nevertheless, a 9-percent increase in crude runs resulted in a gain of 6 percent in production for the light grades of fuel oil. A greatly expanded demand for fuel oils in California was partly satisfied by an 18-percent gain in distillate production. The improvement in the light-fuel-oil output in California was due mostly to a 15-percent increase in crude runs and to a smaller degree to a higher percentage yield. The Appalachian, Oklahoma-Kansas, Arkansas and Louisiana Inland, and Rocky Mountain refinery districts produced less light fuel oil in 1943 than in 1942, and gains reported for the Indiana-Illinois and Louisiana Gulf areas were relatively unimportant.

Refiners responded to war needs in 1943 by producing more residual fuel oil in all districts, especially in the East Coast, Indiana-Illinois, Texan Inland, Texas Gulf, and California areas. A 23-percent increase in heavy-fuel-oil output was reported for the East Coast—a gain made possible largely by greatly expanded crude runs, as the yield of 28.8 percent for the area was little above the 1942 level. There was a 7-percent increase in heavy-fuel-oil production for the Indiana-Illinois refinery district due to a higher yield of 22.5 percent in 1943 compared with 21.0 percent in 1942. All of the respective percentage gains in residual-fuel-oil production in 1943—37 percent for the Texas Inland district, 16 percent for the Texas Gulf, and 22 percent for California—were realized both by the processing more crude petroleum and an upward adjustment in percentage yields at the expense of possible gasoline production. Percentage gains in heavy-fuel-oil output were reported for all other refinery districts, but the respective increments were less outstanding.

Crude petroleum (usually low in gasoline content), used in some producing areas in lieu of fuel oil, must be counted as additional supply in fuel-oil statistics. The term "transfers" is applied to crude oil burned direct as fuel, as it covers quantities transferred from the crude oil to the fuel-oil account on the oil companies' books. Crude petroleum may be transferred to the distillate or the residual-fuel-oil account, depending on its "gravity" and the purpose for which it is used. Transfers of distillate grade, consumed as fuel on pipe lines, were reported in areas east of California for a total of 3,051,000 barrels in 1943—a gain of 23 percent over the 1942 quantity of 2,484,000 barrels. A small amount—19,000 barrels—was similarly used in

California in 1943. More important volumes of crude petroleum burned in place of residual fuel oil on leases and by industrial plants were indicated for California and other areas. The California transfers of heavy crude totaled 18,861,000 barrels in 1943—a gain of 29 percent over the 1942 comparative item—and in areas east of California there was a gain of 13 percent—5,226,000 barrels in 1943 compared with 4,625,000 in 1942.

The building of many new tankers, the release of some vessels from military use, and the driving of enemy submarines from coastal waters were all favorable factors that made possible the receipt of 42,566,000 barrels of fuel-oil imports in 1943—a 93-percent gain over the greatly curtailed total of 22,068,000 in 1942. Imports of both distillate and residual grades showed important expansion in 1943. Receipts of distillate fuel oil increased from 3,636,000 barrels in 1942 to 15,999,000 in 1943—the latter quantity representing 7 percent of the total supply of light fuel oils from all sources in 1943 compared with a 2 percent share in 1942. Heavy fuel oils received from foreign countries totaled 26,567,000 barrels in 1943—an improvement of 44 percent over the 1942 quantity of 18,432,000 barrels. Imported residual fuel oil constituted 6 percent of the total supply for the domestic and export markets in 1943 compared with a 4-percent portion in 1942.

The usual sources of supply for fuel oils—production, imports, and transfers from crude oil—were not sufficient to meet total demand in 1943, so a heavy draft of stocks was necessary for a second consecutive year. Total fuel-oil stocks of 90,212,000 barrels at the end of 1943 were approximately 16,500,000 barrels below those held at the close of 1942. It should be added, however, that the liquidation of fuel-oil stocks in 1943 was somewhat below the shrinkage in inventory of approximately 25,600,000 barrels during the critical year 1942. Expressed in still another way, fuel oil taken from storage was used to satisfy about 2 percent of the total demand in 1943 compared with a 4-percent share in 1942. Fuel oil held at the close of 1943 represented a 41-day domestic supply at the December rate of consumption compared with a 55-day "backlog" at the end of 1942. Distillate-fuel-oil stocks at the end of 1943 were equivalent to a 59-day supply compared with about a 62-day quantity at the close of 1942. The residual-fuel-oil inventory was critically low at the end of 1943—a 33-day supply against a 50-day domestic reserve, as of December 31, 1942.

The decline in fuel-oil stocks in 1943 is found more in the residual grades than in the distillate fuel oils. Heavy fuel oils held in storage at the close of 1943 (48,484,000 barrels) were 13,300,000 below the 1942 final inventory, but the lighter fuel oils declined by only 3,200,000 barrels from 44,940,000 in 1942 to 41,728,000 in 1943. The 1943 liquidation of heavy fuel oils was somewhat below the 1942 draft of over 21,000,000 barrels, and about 1,200,000 barrels less light fuel oil were taken from storage in 1943 than in 1942.

Comparative analyses of statistics for distillate fuel oil in the United States, 1942–43, by months and districts

Fluctuations in fuel-oil stocks held in the several refinery districts in 1943 presented a somewhat different picture from the changes recorded in 1942, when normal water-borne movement of supplies to eastern consuming centers was shifted to land routes—tank cars and pipe lines. In 1942 distillate-fuel-oil stocks dropped by more than half in the East Coast, as lack of tankers prevented the usual flow of light grades from the most important producing center—the Texas Gulf Coast—to the eastern seaboard, with the result that supplies piled up in the Gulf area. Improvement in shipping facilities in 1943 allowed a desirable "build-up" in inventory of distillates on the East coast and a liquidation of supplies in the Gulf areas. In 1942 stocks of residual fuel oils dropped drastically by over 21,000,000 barrels because of a 6-percent higher domestic demand, a sharp drop in imports, and the transitional shift in transportation routes. Changed conditions in 1943 allowed some improvement in the residual-fuel-oil stock situation in the East coast area; however, a large shrinkage in the California inventory was repeated for a second year.

Stocks of light fuel oil on the East Coast increased by about 3,900,000 barrels in 1943, in contrast with a 9,600,000-barrel liquidation in 1942. The Appalachian, Indiana-Illinois, and Texas Inland districts reported minor gains in distillates held in storage at the end of 1943 over 1942. Inventories of light oils declined in all other refienry areas, losses being more pronounced in the Texas Gulf and California districts. More than half of the heavy fuel oil is held in California, and there a drop of approximately 9,000,000 barrels in storage supplies in 1942 was followed by a further serious decline of about 17,600,000 barrels in 1943. Put in another way, heavy fuel oil stored in California has shrunk by 50 percent in volume in a 2-year period—from 53,199,000 barrels at the end of 1941 to 26,608,000 in 1943. Minor declines in residual-fuel-oil stocks were recorded for the Appalachian, Oklahoma-Kansas, Texas Inland, and Louisiana Gulf districts in 1943. Residual fuel oil stored in the East coast gained about 2,700,000 barrels in 1943, and a second relative important increase was indicated for the Texas Gulf. Some little improvement in quantity was reported in 1943 for small stocks of heavy fuel oil in the Arkansas-Louisiana Inland and Rocky Mountain districts.

No tanker movements of fuel oil from California to the East Coast were reported for either 1942 or 1943. Rail and truck shipments of distillate fuel oil from the California refinery district (California, Oregon, Washington, Arizona, and Nevada) to other Western States of 435,000 barrels in 1943 differed little from the 1942 total of 423,000 barrels, but the movement of residual grades, which has slumped for several years, increased from 49,000 barrels in 1942 to 215,000 in 1943.

Statistics compiled by the Petroleum Industry War Council and the Petroleum Administration for War covering the movement of fuel oil by tanker, barge, rail (tank car), and pipe line from districts 2 and 3 into the East coast show that the total volume of light fuel oil moved increased by 27 percent from 53,066,000 barrels in 1942 to 67,441,000 in 1943 and that the heavy fuel oil handled in this eastward movement was 75,046,000 barrels in 1943—a 9-percent gain over the 1942 total of 68,686,000 barrels. There was a further serious decline in 1943 in the quantities of both light and heavy fuel oils shipped by tanker from the Gulf Coast to the Atlantic seaboard; however, the loss was more than made up by a phenomenal gain in the tank-car transportation of fuel oils from districts 2 and 3 into the Atlantic Coast States. There were other minor movements of fuel oil to eastern areas by barges operating along the Gulf Coast, barges ascending the Mississippi and Ohio River systems, and tankers and barges on the Great Lakes. No pipe line movement of fuel oil into the East Coast was reported in 1943. The detailed quantities of distillate and residual fuel oils handled in 1942 and 1943 by the several methods of transportation are shown in an accompanying table.

Movement of domestic fuel oils into the East coast (district 1) by tanker, barge, rail, and pipe line, 1942–43

[Thousands of barrels]

Source: Petroleum Industry War Council and Petroleum Administration for War.

Tanker rates for the shipment of fuel oils from the Gulf Coast to the North Atlantic, not east of New York, remained unchanged throughout 1943. Basic rates of 42 cents a barrel for No. 2 light fuel oil and 48 cents a barrel for crude and heavy fuel oil (10°–19.9° gravity) effective since January 19, 1942, were maintained in 1943. A surcharge of 200 percent allowed by the War Shipping Administration "to cover increased wartime operating expenses," starting April 6, 1942, was continued in force all during 1943.

There were relatively few price changes in representative fuel-oil prices in 1943 compared with 1942. The average price of Bunker C fuel oil at New York harbor of $1.61 a barrel for 1942 increased to $1.82 for 1943. The price of $1.65 a barrel dating from September 1942 held until March 9, 1943, when suppliers raised their quotations to range from $1.65 to $2.07 a barrel. This change was made to place prices upon a gravity basis, a departure allowed by Amendment 79 to Revised Price Schedule 88, issued by the Office of Price Administration on March 3, 1943. The new prices ranged from $1.65 a barrel for 9.9° gravity fuel oil to $2.07 for 25.0° gravity. The above schedule of prices for Bunker C at New York harbor remained unchanged until the end of 1943. The New York harbor price of $2.78 a barrel on Diesel fuel for ships' bunkers dating from September 1942 remained at the same level throughout 1943.

[1] Platt's Oil Price Handbook.
[2] No quotations posted.

A price of 85 cents a barrel for Bunker C at Gulf ports, starting in December 1942, was maintained until March 9, 1943, when there was an adjustment to a new schedule—ranging from 85 cents to $1.09 a barrel—based upon the gravity of the product. The monthly average price for Bunker C settled to $1.06 in April, and no changes developed after that month. The quotation of $1.65 a barrel for Diesel bunker fuel at Gulf ports, effective December 1942, was maintained throughout 1943.

Bunker C in California was priced at 84 cents a barrel in June 1942, and no changes were reported until March 12, 1943, when 1 cent a barrel was added. There was a second advance to $1.10 a barrel on June 11, and that quotation remained in force for the balance of 1943. The increases for Bunker C in California in 1943 advanced the average price for the year to 99 cents a barrel compared with 85 cents in 1942. The price of Diesel bunker fuel at California ports ($1.43 a barrel, effective in May 1942) was not changed in 1943.

A quotation for No. 2 straw fuel oil at refineries in Oklahoma (3.63 cents a gallon, starting in December 1942) remained in force throughout 1943.

Monthly retail prices for different fuels in a number of cities are compiled and published by the Bureau of Labor Statistics, United States Department of Labor. The retail price of No. 2 fuel oil in Chicago (7.65 cents a gallon, dating from October 1941) was not changed until December 29, 1942, when a slight advance was made to 7.96 cents a gallon—a quotation that held throughout 1943. The consumer price of No. 2 fuel oil in New York City (8.79 cents a gallon, effective in August 1942) was raised to 9.09 cents a gallon on December 29, 1942, and was kept at that level all during 1943. The 0.3-cent increase in the Chicago and New York retail prices was allowed by the Office of Price Administration in Amendment 15 to Maximum Price Regulation 137 to reimburse dealers for higher fuel-oil handling costs under rationing conditions. The rise in price applied to kerosine, range oil, Nos. 1–6 fuel oils, gas oil, and Diesel fuel sold in 30 Eastern and Midwestern States, where fuel-oil rationing has been in force since October 1, 1942.

LUBRICATING OIL

The total demand for lubricating oil amounted to 40,179,000 barrels in 1941, declined to 37,329,000 barrels in 1942, and rose to 40,322,000 barrels in 1943. Although exports increased from 8,272,000 in 1942 to 8,756,000 in 1943, they were still about 2,000,000 barrels below the pre-war level of 1939.

The domestic demand for lubricating oil, including all consumption by our armed forces, fell from 30,255,000 barrels in 1941 to 29,057,000 barrels in 1942 but rose to 31,566,000 barrels in 1943. The sharp decline in consumption for civilian automotive use in 1942 was continued in 1943 but was more than offset by the steady rise in the demand for industrial and war purposes.

The yield of lubricating oil from crude declined from 2.9 percent in 1942 to 2.7 percent in 1943. Stocks declined by about 1.6 million barrels in 1943. The refinery production of lubricating oil (38,679,000 barrels in 1943) showed virtually no change compared with 1942.

The production of lubricating oil by districts changed materially in 1943 compared with 1942. Production in the East Coast district has fallen from 8.6 million barrels in 1941 to 7.8 million in 1942 and to 7.2 million in 1943. Production in the Appalachian district, after remaining stationary 3 years, dropped to about 5.6 million barrels in 1943—a decline of almost 0.8 million barrels. These decreases were offset by gains in 1943 of 0.7 million barrels in California, of 0.4 million in the Texas Gulf district, of almost 0.4 million in the Illinois-Indiana district, and of about 0.2 million in the Oklahoma-Kansas district.

OTHER PRODUCTS

Wax.—A record domestic demand for paraffin wax in 1943, plus increased exports, could not be met by a higher production, so a draft on stocks was necessary. The supply of wax would have been ample for all demands had not imports dwindled almost to the vanishing point.

The domestic demand for wax (585,830,000 pounds in 1943) surpassed by 7 percent the previous record of 546,204,000 pounds reported for 1942, and exports of wax increased by 13 percent from 153,519,000 pounds in 1942 to 172,799,000 in 1943. Imports of wax have dropped in recent years from 16,542,000 pounds in 1941 to 9,749,000 in 1942 and to an unimportant quantity of 109,000 pounds in 1943. Greatly reduced imports of wax in 1943 forced distributors to draw on stocks to make up the deficit; as a result, quantities held in storage declined from 85,400,000 pounds in 1942 to 82,040,000 in 1943. The lower stocks in 1943 are a turn-about from 1942, when about 10,600,000 pounds of wax were added to storage.

[1] National Petroleum News.

Production of paraffin wax showed an 8-percent gain from 700,560,000 pounds in 1942 to 755,160,000 in 1943. All refinery areas reported increased production of wax in 1943 except the Appalachian, Texas Inland, and Rocky Mountain. The output in the Appalachian area, an important source of supply, declined 15 percent. The two most important districts for wax production, the East Coast and Texas Gulf Coast, showed increased outputs by 16 and 2 percent, respectively. California again became a source of wax in 1943, with a production of 3,360,000 pounds.

Office of Price Administration regulations kept paraffin-wax prices at the same levels in 1942 and 1943. White crude scale wax, melting point 122°–124°, was quoted on the New York market in 1943 at 4.25 cents a pound. Fully refined wax of 128°–130° melting point was 5.6 cents a pound, while the same quality wax of 135°–137° melting point sold at 6.4 cents a pound.

Coke.—A higher output of petroleum coke in 1943 was sufficient to satisfy a slightly expanded demand plus an addition to storage. The production of coke increased by 4 percent—from 1,338,400 short tons in 1942 to 1,388,400 in 1943. There was a corresponding percentage increase (4 percent) in the domestic demand—1,046,400 short tons in 1943 compared with 1,007,300 in 1942—but export requirements declined from 325,300 short tons in 1942 to 317,600 in 1943. Year-end stocks of coke—at a very low level in 1941—increased by 3 percent in 1942 and by 10 percent in 1943 or from 233,800 short tons in 1942 to 258,200 in 1943.

Only three refinery districts produce important quantities of petroleum coke. The Indiana-Illinois district is outstanding and reported 61 percent of the national total in 1943. The Texas Gulf Coast rated second, with 13 percent of the total, and the Oklahoma-Kansas area third, with 9 percent of the output. The Oklahoma-Kansas district was the only one of the three areas to show a decline in coke production in 1943.

Asphalt and road oil.—The domestic demand for petroleum asphalt increased from 6,496,900 short tons in 1942 to 6,558,200 in 1943, and export requirements of 159,200 short tons in 1943 were 40 percent over the 1942 total of 113,800 short tons. Refiners produced 6,756,700 short tons of asphalt in 1943, or 7 percent more than the 1942 total (6,296,500 short tons). Imports of petroleum asphalt declined for the second consecutive year, dropping to 113,000 short tons in 1943 compared with 121,200 in 1942. Stocks of asphalt were 563,300 short tons at the end of 1943 compared with 411,000 for 1942.

The heavy demand for residual fuel oil and curtailed road construction and repair in 1943 were reflected in a greatly reduced production of road oil—the output declining from 8,039,000 barrels in 1942 to 2,295,000 in 1943. The domestic demand for road oil dropped proportionally from 8,484,000 barrels in 1942 to 2,450,000 in 1943, and stocks declined from 348,000 barrels at the end of 1942 to 193,000 for 1943.

Detailed statistics for asphalt and road oil appear in a separate chapter on Asphalt and Related Bitumens.

Production of still gas in the United States, 1941–43, by districts

Still gas.—The production of still gas increased by 10 percent from 284,126 million cubic feet in 1942 to 312,318 in 1943. Refiners used as fuel at their plants 259,316 million cubic feet of still gas in 1942, or 91 percent of the production. The larger quantities of still gas were produced in the following refinery districts, in the order of importance: Texas Gulf Coast, Indiana, Illinois, Kentucky, etc., East Coast, and California.

Miscellaneous oils.—The domestic demand for this group of products has risen steadily from 11,862,000 barrels in 1941 to 14,547,000 barrels in 1942 and 18,395,000 barrels in 1943. About half the total supply comes from refineries, and the remainder represents transfers of liquefied petroleum gases from natural-gasoline and cycle plants that are not included in mortor-fuel demand but classed as sold for fuel uses. Refinery production amounted to 8,117,000 barrels in 1942 and 9,660,000 barrels in 1943, and transfers rose from 7,195,000 barrels in 1942 to 9,699,000 in 1943. The refinery output by products is shown for 1941 and 1942 but is not available for 1943.

Production of miscellaneous oils in the United States, 1941–42, by districts and classes [1]

[1] Detailed figures for 1943 not yet available.

WORLD PRODUCTION[2]

Regained control over the sealanes permitted the production of crude petroleum in the principal United Nations to recover to such an extent that the world output in 1943 was 7 percent higher than in 1942 and exceeded slightly the 1941 output, which held the previous record. The increase was due largely to the 8-percent augmented yield in the United States, which comprised 67 percent of the total in 1942 and 68 percent in 1943. Other North American countries either maintained a stationary output or decreased from 1942 to 1943.

In South America, Venezuela and Colombia increased their petroleum production in 1943 over 1942; but neither attained the level of 1941. Argentina and Peru enlarged their output in 1943 compared with 1942.

Little authentic information is available on petroleum production in Europe; but such data as are at hand indicate greater production in Germany and in Hungary in 1943 than in 1942. Allied air attacks and the continued exhaustion of old fields reduced the production in Rumania. The ravages of war and disorganization of transport are believed to have reduced crude-oil output in the U. S. S. R. from 1942 to 1943.

---

[2] By A. H. Redfield, Petroleum Economics Division, Bureau of Mines.

In Asia, Bahrein Island raised its petroleum production in 1943 but not to the level that prevailed in 1939. The output of Saudi Arabia definitely declined in 1943. Iranian production was a little larger in 1943 than in 1942. Recovered control of the Mediterranean by the United Nations and the reopening of the northern fork of the pipe line permitted Iraq nearly to double in 1943 its output of 1942 and to approximate its pre-war output. In the course of 2 years' uninterrupted control, the Japanese invaders are believed to have restored to a limited extent at least the petroleum production of the Netherlands East Indies and of Sarawak and Brunei.

In Egypt the output of the Ras Gharib field raised the national production to nearly twice the quantity produced in 1939.

Crude petroleum produced in principal countries of the world, 1939–43, in thousands of barrels

FOREIGN TRADE[3]

IMPORTS

Imports of mineral oils, crude and refined, into continental United States increased 77 percent from 1942 to 1943. They constituted 2 percent of the total new supply in continental United States in 1942 and 4 percent in 1943.

Crude petroleum, residual fuel oil, and distillate fuel oil made up 96 percent (revised figure) of the total imports in 1942 and 89 percent in 1943. Venezuela supplied 55 percent of the crude petroleum imported in 1942 and 68 percent in 1943; Colombia 18 percent in 1942 and 22 percent in 1943; and Mexico 27 percent in 1942 but only 10 percent in 1943. Of the residual fuel oil imported in 1942, the Netherlands West Indies furnished 90 percent and Venezuela 5 percent. In 1943 the Netherlands West Indies shipped 95 percent and Trinidad 4 percent of the residual fuel oil imported into continental United States. Of the distillate fuel oil imported, the Netherlands West Indies sent 53 percent in 1942 but 84 percent in 1943; Venezuela 25 percent in 1942 but only 7 percent in 1943; and Mexico 18 percent in 1942 but only 6 percent in 1943. Altogether, the Netherlands West Indies supplied 73 percent of all mineral oils imported into continental United States in 1943; Venezuela 16 percent; Colombia 5 percent; Mexico 4 percent; and Trinidad 3 percent.

The greatest gains were in imports of distillate fuel oil, of residual fuel oil, and of gasoline. Of the gasoline imported in 1943, the Netherlands West Indies provided 88 percent; Trinidad 7 percent; and Peru 5 percent.

[1] Imports of crude as reported to Bureau of Mines; imports of refined products compiled from data of U. S. Department of Commerce; figures may differ slightly from those used throughout other sections of this report.

[2] Subject to revision.

EXPORTS

Continental United States continued to be a net exporter of mineral oils. The excess of petroleum exports over petroleum imports increased from 80,940,000 barrels in 1942 to 85,135,000 barrels in 1943. Although the excess of exports of crude petroleum increased from 21,537,000 barrels in 1942 to 24,508,000 barrels in 1943, the excess of exports of refined oils increased from 59,403,000 barrels in 1942 to 60,627,000 barrels in 1943. Of the refined oils, only residual fuel oil showed greater imports than exports. Imports of residual fuel oil exceeded exports by 6,338,000 barrels in 1942 and by 9,801,000 barrels in 1943.

In absolute amounts, exports and Territorial shipments of mineral oils, both crude and refined, were 27 percent larger in 1943 than in 1942. The principal gains were in outward shipments of motor fuel. This was followed, in order of importance, by residual fuel oil, crude petroleum, and distillate fuel oil.

Of the exports of major refined mineral oils, 63 percent in 1942 and 70 percent in 1943 went to Europe. The United Kingdom received 60 percent of the total in 1942 and 67 percent in 1943; and the U. S. S. R. most of the remainder.

The Southwest Pacific region was the second most important destination of major refined oils exported from continental United States. Australia received 6 percent of the total exports in 1942 and 12 percent in 1943. New Zealand received 3 percent in both years.

Exports to other North American countries declined from 19 percent of the total in 1942 to 8 percent in 1943. Canada received 8 percent of the whole in 1942 and 5 percent in 1943.

[3] Subject to revision.

INTERCOASTAL SHIPMENTS [4]

Receipts of mineral oils, crude and refined, on the East Coast from Gulf Coast ports were only 56 percent as large in 1943 as in 1942 and only 16 percent as large as in 1941. Gasoline was the largest single item in these shipments and constituted 44 percent of the total shipments in 1943. However, shipments of gasoline from Gulf Coast to East Coast ports were 11 percent smaller in 1943 than in 1942. Intercoastal shipments of residual fuel oil declined 52 percent, of distillate fuel oil 27 percent, and of kerosine 43 percent from 1942 to 1943. Shipments of crude petroleum from Gulf Coast to East Coast ports in 1943 were only 17 percent of the quantity shipped in 1942 and only 3 percent of that shipped in 1941.

SUMMARY

The dynamic effects of record war production upon the natural-gas industry in 1943 were felt in continued vigorous expansion of markets. Marketed production increased 10 percent over 1942 to a new high of 3,349,586 million cubic feet, according to current estimates. Use by domestic and commercial consumers exceeded 1942 by 7 and 14 percent, respectively, and total industrial requirements were about 10 percent larger.

Unusual gains of 34 and 26 percent in the quantity of gas consumed as fuel at petroleum refineries and public-utility power plants were indicated in 1943 compared with 1942. Conversions to gas from other fuels (chiefly from fuel oil in the Southwest and California) and greater productive activity at these establishments were contributing factors Miscellaneous industrial (including power-plant) consumption increased 15 percent in 1943 to 1,197,305 million cubic feet. Oil- and gas-field use of gas is estimated to have totaled 760 billion cubic feet in 1943 compared with 721.1 billion in 1942.

Carbon-black and portland-cement plants utilized less natural gas in 1943 than in 1942. Gas consumption declined in the carbon-black industry because of higher average yields per thousand cubic feet of gas burned and in the cement industry because of lower production and conversion to other fuels at several plants.

The average value of natural gas at the wells is estimated to have risen from 5.1 cents per thousand cubic feet in 1942 to 5.3 cents in 1943. A trend toward slightly higher average field prices is evident in nearly all producing districts, and this factor is thought to have more than balanced the depressing effect on the United States average of relatively higher production in 1943 from areas where low prices prevail.

---

[1] In this report the term "billion" is equivalent to 1,000,000,000 and "trillion" to 1,000,000,000,000.

The average value at points of consumption of all gas marketed was 22.7 cents per thousand cubic feet in 1942 and about 22.6 cents in 1943. The unit value of domestic and commercial gas declined in 1943 as in 1942, influenced primarily by larger average consumption per meter which, under the "block" or "incentive" rate schedules in

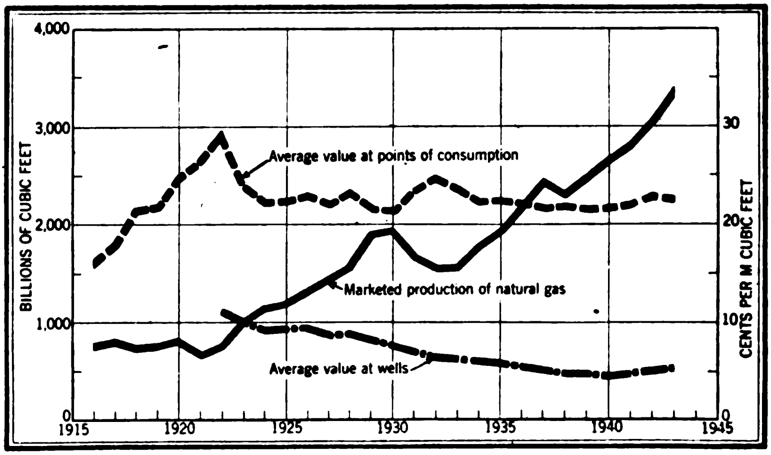

FIGURE 1.—Production and value of natural gas in the United States, 1916–43.

common use, has the effect of reducing average unit costs. The average value of all industrial gas sold increased from 9.5 cents per thousand cubic feet in 1940 to 10.9 cents in 1942 and continued upward to about 11.2 cents in 1943.

Exports to Mexico, largely to the vicinity of Monterey, reached a new high in 1943 at about 9.8 billion cubic feet, a 14-percent increase over 1942. The small movement of natural mixed with manufactured gas from New York State to Ontario, Canada, amounted to 133 million cubic feet in 1943 and 130 in 1942.

The total of all classes of natural-gas consumers increased 2 percent in 1943 to about 11,177,000.

FEDERAL LAW AND ADMINISTRATION

Recent decisions of the United States Supreme Court will dictate fundamental changes in the methods and concepts of utility rate regulation. These decisions are described by the Federal Power Commission as "the most important pronouncements of the Supreme Court in the field of regulatory law in several decades."[3] The concepts of "fair value" and "reproduction cost" are no longer required as factors in establishing a rate base. As a result, proceedings in rate cases will be expedited by the elimination of many technicalities, and regulatory agencies will exercise their discretion and judgment in a broader field.

The Office of War Utilities was established on February 5, 1943, as an adjunct of the War Production Board. Its chief functions are to determine in advance the essential requirements of gas and to arrange, in cooperation with the Federal Power Commission and the Natural Gas and Natural Gasoline Division of the Petroleum Administration for War for such added supplies and facilities as may be needed to satisfy them.

The Director of the Office of War Utilities was authorized by the War Production Board to prohibit delivery of gas to such industrial plants as failed to provide stand-by facilities and fuel or to convert gas-fired equipment to less critical fuels when practicable. The use of some strategic mineral products was restricted, and materials for repairs, maintenance, and extension of plant were limited by a system of allotments. Late in 1943, however, a tendency developed toward more liberal allotments of certain steel products. More latitude in drilling new wells was permitted in Michigan, eastern Kansas, southern Oklahoma, and north and west central Texas by supplementary orders of the Petroleum Administration for War.

---

[3] Federal Power Commission, The First Five Years under the Natural Gas Act: 1944, p. 3.

The Office of Price Administration required prior notice from utilities of all proposed changes in rates. On June 15, 1943, this office rationed stoves burning gas, oil, coal, or wood. Manufacturers were allowed to produce and sell new units for cooking and heating stoves after September 1, provided that the materials used were already in stock or were acquired by authority of the War Production Board.

By order of the Securities and Exchange Commission, five subsidiaries operating in the Appalachian region were separated from the Standard Oil Co. (New Jersey), and formed into the Consolidated Natural Gas Co. The new company is one of the largest single operating units in the natural-gas industry.

GROSS PRODUCTION

The estimate of gross production of natural gas from gas and oil fields in 1942 indicates a 9-percent increase over 1941 to 4,453,900 million cubic feet. Gains in Texas represented 50 percent of the total increase for all producing States. The only substantial decline was in Illinois, where production of gas in the oil fields reached a peak in 1940.

The output of gas wells in 1942—2,875,090 million cubic feet—exceeded the revised 1941 record by 15 percent. Since 1938 the rise in gas-well production has been very rapid, stimulated chiefly by progressively greater demands from gas pipe-line systems and by the sharp uptrend in cycle-plant operations in Texas and to a lesser degree in Louisiana. The estimated production of gas from oil wells in 1942 was 1,578,810 million cubic feet—2 percent less than the revised 1941 total. Since 1938 the increase in this type of production has been small; larger output in some States, notably Louisiana and Texas, have been partly offset by reductions in others. As a result of these changes, the ratio of gas-well production to the total has increased from 51 percent in 1938 to almost 65 percent in 1942.

Repressuring and pressure-maintenance operations continued their expansion of recent years. The return of gas for these purposes to reservoirs was reported in 16 States in 1942, and the total volume increased 17 percent over 1941 to 755,971 million cubic feet. Although the magnitude of cycle operations in Texas and Louisiana tends to dominate the statistics, steady growth in repressuring is widespread in other producing areas and significant of improving methods in oil production.

The reported quantity of gas stored in natural reservoirs increased 9 percent in 1942 to a new record of 17,672 million cubic feet. Moderate increases were reported in six States, and Arkansas was added to the list of States reporting gas storage.

In September 1943 the quantity of natural gas in storage in the Appalachian region reached a peak of over 63 billion cubic feet, *Gross production and disposition of natural gas in the United States, 1941–42, by States, in millions of cubic feet*

[1] Marketed production plus quantities used in repressuring, stored in ground, lost, and wasted (see footnote 2).

[2] Includes gas (mostly residue gas) blown to the air and transportation losses, but does not include direct waste on producing properties, except where data are available.

[3] Includes gas transported from other States.

[4] Revised figures.

[5] North Dakota, South Dakota, Tennessee, Utah, and Virginia.

according to the Office of War Utilities, exclusive of the "gas cushion" which in operating practice is allowed to remain in the reservoirs as unavailable for distribution. Storage operations in this region in 1943 included the injection of over 22 billion cubic feet of gas in the May-September period and the withdrawal of 20.3 billion to meet the heavy demand during the cold months. In all, 44 fields are equipped as storage points for use in this program. To replenish stored supplies, many gas wells which were formerly shut in during the summer months are now producing throughout the year. It is generally conceded that gas storage has played a vital part in supplying the gas needs of war industries and others in this territory during the past two critical winters.

In other parts of the country storage of natural gas is not extensively used to meet peak-load requirements, except in Kansas. However, a few scattered fields in other States are utilized for this purpose.

The estimates of losses and waste in 1942, based upon available evidence, indicate a slight decline in the total to 626,782 million cubic feet from 1941. Material reductions are shown in Illinois and Oklahoma, conforming to declining trends in gas production from oil fields, and in California, where 21 billion cubic feet more gas were returned to oil sands for repressuring in 1942 than in 1941, with a comparable saving of gas formerly blown to the air. Compensating increases in losses and waste are indicated in Louisiana, New Mexico, and Texas. In March 1944 the Railroad Commission of Texas estimated that about 1 billion cubic feet of gas per day were being wasted to the atmosphere in Texas by being blown or flared.

MARKETED PRODUCTION

Increasing war activities caused a marked expansion in demand for natural gas during 1942. Marketed production increased 9 percent over the 1941 record in spite of shortages in manpower and equipment. Most of the producing States reported increased output, notable exceptions being New York with a 17-percent and Mississippi with a 51-percent decline. Available reserves are being rapidly depleted in these two States. Major producing States showing material gains in 1942 over 1941 were: New Mexico (21 percent); Kentucky (16 percent); Oklahoma (15 percent); Louisiana (11 percent); and Texas, California, and Ohio (8 percent each). Texas, Louisiana, California, Oklahoma, and West Virginia, in order of production, maintained the same rank as in 1941.

Natural gas produced in the United States and delivered to consumers, 1938–42 by States, in millions of cubic feet

States furnishing the largest proportion of their gas to consumers outside of their borders were: West Virginia, with 66 percent of production shipped out; Louisiana, with 46 percent; and Texas, with 25 percent. These three States furnished 60 percent of the total output of the United States in both 1942 and 1941.

The average value of gas at the wells was 5.1 cents in 1942 compared with 4.9 cents in 1941 and was the highest since 1937, when the same figure was recorded. It is probable that 1940 was an important turning point in the long-term trend in the wellhead price of gas. In that year a decline of many years' duration culminated in a low of 4.5 cents per thousand cubic feet. Changing field conditions suggest firmer price tendencies for the future. The average value at points of consumption was 22.7 cents in 1942 compared with 22.1 cents in 1941.

Natural gas produced and consumed in the United States in 1942, by States

[5] Includes 7,390,000 M cubic feet piped to Mexico.

WELLS

Reported gas-well completions in 1943 (2,290) were 12 percent below 1942 and 21 percent below the 1941 peak of 2,911. Drilling for gas has declined since 1941 in nearly all States, under the influence of spacing regulations and restricted supplies and manpower. Exceptions are Pennsylvania, where the need for gas has been urgent, and California, where dry-gas development is growing in importance. In West Virginia the rapid decline in drilling in the deep Charleston gas field has obscured increased activity in smaller fields.

The number of producing gas wells in the United States increased from 55,500 at the end of 1941 to 56,150 on December 31, 1942. The net gain of 650 wells subtracted from 2,597 completions during 1942 indicates the abandonment or shutting-in of 1947 wells in that year. To the extent that old wells may have been returned to production in 1942, the actual number of wells that ceased to produce may have been larger.

Gas wells in the United States, 1941–43, by States

TECHNOLOGIC DEVELOPMENTS

Many materials can be made from natural gas by cracking it into its various hydrocarbons and bringing them together in different combinations. Continued experiment and research by chemists in 1943 resulted in the discovery of new products, new uses for those previously found, and improved methods of production.

Carbon black, valuable in the production of synthetic rubber products, was produced in large quantities as a byproduct of the pyrolytic cracking of natural gas to produce hydrogen.

A plastic called polythene, which can be made from coal and petroleum, was also made from natural gas. It has properties that fit it for varied uses. In thin sheets it is flexible enough for toothpaste tubes, waterproof coatings, and wire insulation. In thick sheets it is stiff enough to be used as a rigid plastic. Other plastics that can be substituted for strategic materials and to supply nondefense industries have also been developed from natural gas.

Several large plants are using natural gas as fuel in the production of magnesium, a light metal now extensively used in building airplanes and the production of ordnance materials.

When gas hydrocarbons are liquefied, valuable materials, such as benzine, toluene, and the heavier aromatic products may be obtained. These were formerly produced only by carbonizing coal. Improved techniques of extracting and treating liquids from natural gas indicate that the production of liquid motor fuel from methane may become economically feasible under favorable conditions before many years.

The use of natural gas as a fuel for dehydrating foods continued to increase rapidly under the influence of war. The armed forces have demanded vast quantitites of dehydrated foods in wide variety for shipment overseas, chiefly because they permit a great saving in shipping space over fresh or canned products.

New or expanded applications of gas by metalworking industries have been numerous and have often speeded the production of war goods. Among these were larger and more complex radiant tube furnaces and the use of controlled atmospheres containing fuel gas to eliminate oxide formation on steel, to carburize steel surfaces, and to "pickle" steel sheets for better adherence of zinc and other coatings. A process of heat-treating metal shapes by impact of a gas flame was developed to reduce greatly the time required over conventional furnace methods.

POST-WAR PLANS

Progressive members of the natural-gas industry are planning post-war activities, even when meeting present war emergencies. Studies are being made to determine the effects of national trends upon gas markets in different sections of the country and the most efficient means of distributing and utilizing gas. Methods of stimulating sales are being considered and coordinated with the results of detailed analyses of gas markets, rates, distribution costs, and competitive influences. Greater emphasis upon advertising is anticipated, particularly of the type directed at specific groups of potential consumers.

Many innovations are being introduced in new designs for appliances and equipment which will include the use of new plastics and other substitute materials. Closer relations between the utilities and gas-appliance manufacturers may result in more efficient home appliances.

Gas air-conditioning units suitable for homes and small business establishments have been developed in readiness for manufacture and sale when industry resumes peacetime activities. The cost per unit is too high to attract a broad market, but demand may be sufficient to facilitate substantial cost reductions as the volume of production grows.

The post-war future of the two large Government-owned pipe lines that now transport crude oil and petroleum products from Texas to the eastern seaboard has been the subject of much speculation within the oil and gas industries. It has been proposed that one or both lines be converted to natural-gas service after the emergency.

REVIEW OF FIELD DEVELOPMENTS, BY STATES

Arkansas.—There were 3 gas completions in northwest Arkansas in 1943 compared with 1 in 1942. Two wells were drilled in Franklin County, with initial productions of 35 and 33 million cubic feet, respectively, at depths of 1,345 and 1,380 feet. One well in Johnson County was completed at 3,260 feet for an initial production of 1 million cubic feet. Five other tests in the northwest area were dry. The 21 dry-gas fields in the region averaged about 15 million cubic feet daily production during the year.

One gas well was completed in southern Arkansas in Union County at a depth of 3,564 feet. It produced 25 million cubic feet initially. The southern oil and gas fields produced about 111 million cubic feet of gas a day during 1943, a substantial increase over 1942. A plant for removing the hydrogen sulfide from sour gas is operating in the McKamie field. It is estimated that about 25 million cubic feet of sweet gas are being converted daily from 30 million cubic feet of sour gas. A second plant 7 miles southwest of Magnolia will convert the sour gas from the Dorcheat and Macedonia fields into commercial fuel, partly for use in war plants.

Production in Arkansas increased 54 percent from 29,560 million cubic feet in 1942 to 45,640 million in 1943. The southern counties supplied 88 percent and the northwest area 12 percent of the total. Production from the gas fields decreased 2 percent from the 1942 output of 5,367 million cubic feet to 5,259 million, whereas output from the oil fields increased 67 percent from 24,193 million cubic feet to 40,381. Columbia County, with 25,250 million cubic feet, more than doubled the 1942 record and displaced Union County as the largest source of gas. Johnson County, with 2,388 million cubic feet, ranked first in the northwest area; and Pope County, with 1,064 million, displaced Crawford in second place.

Information relative to natural-gas developments in Arkansas during 1943 was supplied by Joe W. Kimzey, State geologist, from records of the Arkansas State Department of Revenues.

California.—The following information was taken from a report from E. F. McNaughton, California Railroad Commission:

Because of insufficient supplies of oil in California following unusually heavy requirements during 1943, both high- and low-gravity fields were drilled in search for new supplies, and drilling for gas had secondary importance. There were no major discoveries, but some small fields were added to gas production.

A well was completed in the Hamilton zone of the Rio Vista dry-gas field, but little was added to the meager information available about the formation. Three relatively shallow dry-gas zones were found in the El Segundo field in the Los Angeles Basin at a depth of 2,200 to 4,300 feet. Dry gas was discovered in areas near Mendota and Firebaugh, Fresno County, and small areas were opened in Butte and Glenn Counties. A new well in the Buttes area helped the failing output there. Two dry-gas wells near Willow were tapped to supply that community.

Declining production from the Marysville Buttes and the Rio Vista dry-gas fields caused utilities serving northern and central California to make new pipe-line connections, to reinforce lines to carry higher pressures, and to make shifts in their transportation systems so that auxiliary supplies could be obtained from other sources.

Equipment was installed in several gasoline plants in southern California to eliminate waste and to increase line pressures so that the residue gas could be delivered direct to transmission lines serving the Los Angeles and Santa Maria areas and to the Goleta storage project and thus, by substitution, make more gas available in other areas for consumption or for storing.

Underground storage in the Playa del Rey field, which was begun in 1942, was continued in 1943. At the close of the year, 1,731 million cubic feet of gas had been injected into the field and about 121 million withdrawn. There is some indication that all the gas injected will not be recoverable, but this cannot be determined until injections and withdrawals have been checked over a longer period than is possible at present.

A study of peak-day demands estimated under minimum temperature conditions in both northern and southern California was made by the commission to determine whether the gas supply in the State was adequate. It was concluded that an estimated firm, noncurtailable demand of 1,258 million cubic feet could be met by natural-gas distributors, with the help of stand-by manufactured-gas plants. The total potential peak-day demand was estimated at 1,890 million cubic feet in 1943 compared with 1,635 in 1942. Natural gas reserves in California are estimated at a revised figure of 11,927,774 million cubic feet.

No figures of production are available for the full year 1943, but comparison of records for the first 6 months of 1942 and 1943 shows a 13-percent increase. Dry-gas production continued to increase, and a 47-percent gain over the 1942 record is indicated by available figures. Withdrawals from the Rio Vista dry-gas field supplied 83.8 percent of the total dry gas produced in California in 1943. Repressuring was continued during the year, stimulated by the emphasis placed upon conserving liquid petroleum products. Withdrawals from fields having high gas: oil ratios continued to be restricted, except during emergency periods. Efforts are being made to reduce the volume of gas wasted. A purification plant with a daily capacity of about 30 million cubic feet is being installed in the Coalinga field, where 30 to 50 million cubic feet of gas have been blown to the air monthly because its hydrogen sulfide content rendered it unfit for market.

Gas sales in California totaled 303,621 million cubic feet in 1943—a 15-percent gain over the 1942 record. The number of gas customers increased 3 percent over the 1942 figure to 2,034,930. When gas supplies failed to meet peak loads during the winter of 1943, a large number of industrial plants had their deliveries curtailed in favor of firm and war-production customers. More plants in southern California were affected by the shortage than in any previous period. The use of gas as fuel in electric generating plants was increased materially during the year to conserve petroleum.

Colorado.—Ernest A. Hanson, supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo., reports only one gas completion in Colorado in 1943. This was an exploratory well at Douglas Creek, Rio Blanco County, which had been drilled to the Weber quartzite at a depth of 8,558 feet in 1942 in an unsuccessful search for oil. A gas well was developed in 1943 by plugging back the hole and perforating opposite three sands in the Dakota and Lakota formations at a depth of 4,326 to 4,430 feet. The initial production of the completed well was 5,800,000 cubic feet per day and the shut-in pressure 1,680 pounds. It will not be used until the proved gas reserves of northwestern Colorado justify the building of a pipe line to a profitable market.

The Hiawatha and Powder Wash fields, whose output increased 38 and 39 percent, respectively, over 1942, furnished 96 percent of the marketed production in Colorado during 1943. Production by fields, in millions of cubic feet, follows: Hiawatha, 3,714; Powder Wash, 1,527; Thornburg, 171; Berthoud, 43; and Craig 5.

Gross output in Colorado in 1943 was 6,148 mllion cubic feet—40 percent over the 1942 record of 4,387 million. It is estimated that 273 million cubic feet were used for repressuring or were recycled. Field use was reported as 175 million cubic feet for the year compared with 54 million in 1942. Estimated losses have declined 21 percent from 304 million cubic feet in 1942 to 240 million in 1943. There is still surplus gas in the Wilson oil field, where the gas: oil ratio averaged 368 cubic feet of gas to 1 barrel of oil.

Marketed production totaled 5,460 million cubic feet, 35 percent over the 4,030 million reported in 1942.

Illinois.—Natural-gas developments in Illinois during 1943 were reported by A. H. Bell, geologist, and C. W. Carter, assistant geologist, Illinois Geological Survey.

Five wells, all producing from the Bridgeport sand, were drilled in the Russellville gas field during the year, making a total of 59 in that area. The initial production of the new wells averaged 3 million cubic feet of gas a day. At the end of the year, 1,650 acres of the Buchanan and 270 acres of the Bridgeport sand were proved by drilling.

The Ayers field in Bond County, with one gas completion in 1943, had nine producing wells altogether. Gas comes from the Bethel sandstone at an average depth of 950 feet.

A major part of the casinghead gas from the oil fields is treated for natural gasoline, but as yet only a small percentage of the residue gas is used. The Louden field had an average daily production of 15 million cubic feet in 1943, most of which was processed for gasoline. The output in 1942 averaged 20 million cubic feet a day. A pipe-line company distributed part of the residue gas at the rate of 1.4 million cubic feet a day in 1943 and 1.9 million in 1942. The same company also took 90 thousand cubic feet a day in 1943 and 50 thousand in 1942 from a well in the field which produces from a basal Pennsylvanian sandstone. The total production of the field was 7 billion cubic feet in 1943 compared with 8.4 billion in 1942.

Production from the Salem field is estimated at 20 billion cubic feet and averaged 37 million cubic feet a day at the end of the year compared with 23.7 billion produced in 1942 and a daily average of 63 million at the end of the year. Three gasoline plants processed approximately 35 million cubic feet daily in 1943, 6 million of the residue being used for repressuring and 1 million being distributed to nearby towns. In 1942, 49.8 million cubic feet were processed daily, 5 million of the residue being used for repressuring and 0.8 million being distributed.

In the Dale-Hoodville Consolidated field of Hamilton County, 6.2 billion cubic feet of gas were processed from a total output of 7 billion cubic feet. Only 51 million cubic feet of the residue gas were used for repressuring, the remainder being flared.

In the Benton field of Franklin County, 320 million cubic feet of a total 3 billion produced were processed for gasoline. There were no repressuring operations in that area, and no residue gas was sold.

Eight billion cubic feet were produced in the New Harmony Consolidated field of White County, of which 4.9 billion were processed. Only 1.8 billion cubic feet of residue gas were returned to the producing sands. None was sold. Production in 1942 totaled 8.7 billion cubic feet.

Approximately 62 billion cubic feet of gas were produced in Illinois during 1943 from fields discovered after January 1, 1939, compared with 84.4 billion in 1942. A large part of the output was burned in flares. Marketed production in the State totaled 2,410 million cubic feet—a 6 percent decrease from the 1942 figure. Output by fields, in millions of cubic feet, was: Russellville 1,236, Ayers 14, Salem 650, and Louden 510. Forty-eight percent of the total amount was casinghead gas from the oil fields.

Indiana.—There were no new gas developments of importance in Indiana during 1943, according to Ralph E. Esarey, State geologist, and P. Hastings Keller, assistant State geologist, Indiana Department of Conservation.

Only 19 gas wells were drilled in the State during the year, and all were in the old Trenton area; 21 were drilled in 1942 and 56 in 1941. The total initial production of the new wells (2,562,000 cubic feet) was 77 percent less than that of the completions in 1942 (11,148,500 cubic feet).

Figures on natural-gas production in Indiana are not complete for 1943. The output of the three largest gas fields, in order of rank, was as follows: Rockport in Spencer County, 500,151,000 cubic feet; Greensburg in Decatur County, 228,894,100; and Unionville in Monroe County, 168,710,000. These figures indicate a 14-percent decline from the 1942 output.

A total of 1,700,923,000 cubic feet of casinghead gas from the Griffin field was processed at a natural-gasoline plant on the Illinois side of the Wabash River. This gas probably was returned to the producing sands in the field for repressuring.

Kansas.—Phillip Kaiser, geologist, Kansas Geological Survey, reports 43 gas wells and 12 combination gas and oil wells drilled in Kansas in 1943. This compared with 88 completions in 1942.

The number of gas and combination wells drilled in western Kansas pools was: Zenith-Peace Creek, four; Chitwood, and Medicine Lodge, three each; Burrton, two and Belpre, Canton North, Deerhead, Farmington, Kipp, Kraft-Prusa, and Vernon North, one each. Gas completions in eastern Kansas pools, were: Wyandotte County, five; Allen, Cowley, and Douglas, two each; and Leavenworth (exclusive of McLouth), one.

Ten gas wells were completed in the Hugoton field of Kansas during the year—6 in Kearny County and 4 in Stevens County—compared with 21 in 1942. The combined daily capacity of the new wells was 199.6 million cubic feet. The field had a total of 336 commercial gas wells, with a combined open flow of about 4.2 billion cubic feet at the end of 1943, and had supplied 350 billion cubic feet of gas since its discovery in 1922. It is estimated that 1,500,000 acres have been proved, but at present withdrawals are from only 217,600 acres. The producing formation—three to five zones of porous limestone and dolomite of the Chase group (Permian)—lies at an average depth of 2,750 feet.

Ten gas wells were drilled in the McLouth field during the year compared with 44 in 1942. Being close to the industrial centers of northeastern Kansas, this pool has had its reserves heavily drawn upon. The proved area was extended during the year by a well 2 miles east of previous production, which opened the Jarbalo pool in Leavenworth County. The initial daily potential of the well was 10 million cubic feet. Two more gas wells were drilled in this pool by the end of 1943. The producing sand is in the lower Cherokee shale (Pennsylvanian), at an average depth of about 1,250 feet.

Three wells, two producing both gas and oil, were completed in the Cunningham-Cairo field in 1943 compared with four in 1942.

Another gas pool, the Chegwidden, was discovered in Russell County, western Kansas, by a completion having an initial daily potential of 10 million cubic feet.

The Conservation Division of the Kansas Corporation Commission reports 122 billion cubic feet of natural gas produced in Kansas in 1943, 18 percent over the 103 billion reported in 1942.

Production by major fields, in billions of cubic feet, follows: Hugoton, 63.4; Medicine Lodge, 13.7; Otis, 13.3; Cunningham, 9.4; Burrton, 6.4; McLouth, 2.6; and Alden, 2.1. The output of the Hugoton field increased 53 percent over that of 1942 and was over half of the State total. The McLouth pool produced only about half as much as in 1942. Production in eastern Kansas is estimated at 6.5 billion cubic feet in 1943.

Kentucky.—Mrs. Louise B. Freeman, assistant State geologist, Department of Mines and Minerals, has reported natural-gas developments in Kentucky in 1943.

There were 210 gas wells drilled in 17 counties during the year, the same number as was reported drilled in 9 counties in 1942. Two wells completed in Knox County were some distance southeast of proved territory and increased the known reserves of that area. The remainder were in previously discovered gas fields. Completions in the most active counties were: Pike 75, Knott 31, Floyd 27, Martin 27, Johnson 8, and Jackson 7. These counties ranked the same as in 1942, except that Knott and Floyd changed places, and Johnson displaced Clay and Jackson in fifth place. Gas developments in western Kentucky continued to be negligible.

The only new source of marketed gas was the Jackson County field, which has been developed since 1934 but never used. The first pipe-line connection was made in November 1943.

Producing formations in the Big Sandy gas field of Johnson, Magoffin, Morgan, Breathitt, Clay, and Knox Counties, eastern Kentucky, and the percentage of total wells, including dry holes, drilled to each, exclusive of the Wier and Corniferous production, are as follows: Black Shale (Chattanooga) 62 percent; Maxon Sand (Mauch Chunk) 11; "Salt Sand" (Pennsylvanian) 7; "Big Lime" (Mississippian) 7; and miscellaneous (including Big Six, Big Injun, and Berea) 3. Of the total wells drilled in the Big Sandy field, 11 percent have been dry holes.

Natural gas has been stored underground in Kentucky since 1918. A gas field in Menifee County was first used for that purpose and is still maintained as a reserve, although at present it is not often drawn upon. Another field in Meade County is used to store a reserve supply for Louisville during periods of peak demand. The structure of both fields is such that there is little danger of leakage.

Waste of gas with the production of oil was small in western Kentucky and has been practically eliminated in eastern Kentucky.

Figures of gas production for 1943 were not reported.

Louisiana.—The major part of the drilling in Louisiana in 1943 was in search of crude-oil production, and many of the gas wells drilled were a disappointment from the point of view of the producers. Eleven new fields producing gas or gas distillate were added to producing areas in the State during the year. Of these, six were in the southern area. New gas distillate fields were opened in Beauregard, St. James, and St. Landry Parishes, and a new gas area was opened by a well with an estimated open flow of 45 million cubic feet in northern Louisiana, northwest of Ruston, Lincoln Parish. Five parishes in Louisiana now produce gas only, and 33 produce gas and oil.

In all, 85 gas wells were reported as drilled in Louisiana in 1943, 66 in the northern and 19 in the southern part of the State.

H. W. Bell, director, Louisiana Division of Minerals, has supplied the following information:

Total natural-gas production in Louisiana in 1943 was 699,082 million cubic feet, of which 515,010 million (74 percent) were produced from gas wells and 184,072 million (26 percent) from oil wells. In 1942 total production was 669,136 million cubic feet, of which 463,695 million (69 percent) were from gas wells and 205,441 million (31 percent) from oil wells. These figures show a gain of 4 percent in the total output, an 11-percent gain in the volume of gas produced from gas wells, and a 10-percent loss in the volume produced from oil wells.

Of the gross total in 1943, 91,144 million cubic feet were returned to the producing sands, and 97,617 million were flared or vented to the air, leaving 510,321 million to be marketed or used.

Michigan.—Seven gas fields were discovered in Michigan, and one old field was extended during 1943, according to a report submitted by F. R. Frye, petroleum engineer, Michigan Department of Conservation.

The Cranberry Lake field in Clare and Missaukee Counties had 21 wells drilled and 3,360 acres proved. The Woodville field in Newaygo County had over 800 acres proved by five new wells. The other discoveries were in Gratiot, Mecosta, Montcalm, and Osceola Counties. A discovery well with an initial production of 10,400,000 cubic feet of gas was drilled in the Goodwell field in Newaygo County. It was finally deepened and completed as an oil well. In four of the new fields no wells in addition to the discovery had been completed at the end of the year.

Only 47 gas completions, all in the Michigan Stray sand, were reported in 1943 compared with 74 in 1942. More than half of the new wells were in Clare and Newaygo Counties.

The Austin field in Mecosta County is being used for gas storage.

It is reported that over 4 billion cubic feet have been returned to the Michigan Stray sand, bringing the pressure back almost to the original shut-in pressure of the field.

Pipe-line construction in Michigan in 1943 was limited to connections between gas fields and distribution lines, except for a line connecting the Austin gas pool storage project with the Six Lakes field.

Natural-gas production in Michigan reached a new peak of 19,581,420,000 cubic feet in 1943, 10 percent over the 1942 figure of 17,749,249,000 cubic feet.

Mississippi.—H. M. Morse, supervisor, State Oil and Gas Board, reports that no gas wells were drilled in Mississippi during 1943.

All of the wells in the Jackson field, still the main source of gas in the State, are producing salt water with the gas. Four wells were abandoned, leaving 19 producing. Rock pressure is about 900 pounds.

A total of 18,645,000 cubic feet of casinghead gas was flared in the oil fields.

Production from the Jackson field was 1,349,936,000 cubic feet. Gross production for the State was 1,368,581,000 cubic feet.

Missouri.—According to Frank C. Greene, geologist, Missouri Geological Survey, five gas wells were drilled in Missouri in 1943 compared with seven in 1942. All of the new wells were in Jackson County, which had no completions in 1942. Their initial open flow was 760,000 cubic feet daily.

A 7-mile pipe line from the Prairie Point pool in Platte County to the industrial district of Fairfax was completed during the year.

A study was made of the Polo field, discovered in 1940, but no pipe-line connections have as yet been made.

Montana.—Data on natural-gas developments in Montana during 1943 were taken from a report by Ernest A. Hanson, supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo.

There were 51 gas completions during the year, a 26-percent decline from the 1942 record. Bowdoin and Cedar Creek fields reported 40, Marias River 3, Davon and Cut Bank 2 each, and Haystack Butte, Ingomar, Kevin-Sunburst, and Whitlash 1 each. The combined open-flow capacity of the new wells was 64,640,000 cubic feet.

The wells drilled in the Marias River field extended the proved territory about 4 miles northeastward. The field was discovered in 1940, but the gas was not used commercially until December 1943, when it was turned into the pipe line that supplies Shelby. Gas is found in a 5-foot sand in the Colorado shale, at an average depth of 1,300 feet.

The discovery well drilled at Ingomar in the northwestern part of Rosebud County was reported as producing noninflammable gas from the Amsden formation at a depth of 3,800 to 4,119 feet.

Gross production in Montana in 1943 totaled 31,597 million cubic feet, 2 percent over the 31,012 million reported in 1942. Repressuring accounted for 35 million, field use for an estimated 1,038 million, and losses for an estimated 199 million, of which 150 million were in the Cut Bank field. There was a 4-percent decrease in the volume of gas treated for natural gasoline, but a 1-percent increase in the quantity of gasoline extracted. A plant in the Cut Bank field treated 11,434 million cubic feet of gas in 1943 to produce 2,737 thousand gallons of gasoline. Another plant in the Dry Creek field treated 90 million cubic feet to produce 55 thousand gallons of gasoline.

Marketed production totaled 30,325 million cubic feet, only 415 million over the 1942 record. Output decreased in all fields except Bowdoin, which increased 14 percent, and Cut Bank, which increased 12 percent. The Cut Bank field supplied 50 percent of the total output in 1943 compared with 45 percent in 1942. Marketed production, by fields, in millions of cubic feet was: Bowdoin 3,563, Bowes 454, Box Elder 482, Cedar Creek, 6,221, Cut Bank 15,205, Devon 356, Dry Creek 995, Hardin 87, Haystack Butte 68, Kevin-Sunburst 1,901, and Whitlash 993.

New Mexico.—L. G. Snow, supervisor, Geological Survey, United States Department of the Interior, Roswell, N. Mex., reports three gas wells (one in Eddy and two in Lea County) drilled in southeastern New Mexico in 1943 compared with eight in 1942. The initial production of the Eddy County well was 1,000,000 cubic feet and the combined initial output of the Lea County wells 7,130,000 cubic feet. Production in Lea County was found in the formations of upper Permian age.

Five wells (all in San Juan County) were completed in the northwestern part of the State compared with four in 1942. Three found gas in the Pictured Cliffs sand of the Fulcher Basin field and two in the Dakota sand of the Barker Creek field. Their total initial production was 9,378,000 cubic feet.

In southeast New Mexico 98,859 million cubic feet of gas were treated for natural gasoline and 47,173 million cubic feet of the residue gas were sold to domestic, commercial, and industrial consumers.

Comparable figures for 1942 are 103,704 and 44,132 million, respectively. Gas used for gas lift, field consumption, and vented without treatment for gasoline totaled 40,000 million cubic feet, a 15-percent decline from the 1942 record. There were two pressure-maintenance projects in Lea County under which 1,565 million cubic feet of residue gas were returned to oil-producing formations and recycled to gasoline plants. In Eddy County 1,027 million cubic feet were injected without being treated for natural gasoline.

Consumption by domestic, commercial, and industrial consumers in southeast New Mexico increased 59 percent from 44,207 million cubic feet in 1942 to 70,448 million in 1943.

Gas used for gas lift, field consumption, and vented without being treated for gasoline in northwestern New Mexico was only 50 million cubic feet in 1943 compared with 125 million in 1942. Domestic, commercial, and industrial consumption totaled 4,807 million cubic feet, 20 percent over the 1942 record.

Total production in Lea and Eddy Counties in 1943 was about 6 percent and in San Juan County about 17 percent above the 1942 output. The total for the State increased about 7 percent.

New York.—The prospects for finding new production in New York are discouraging, according to C. A. Hartnagel, State geologist. Only 2 producing wells, both in Tompkins County, were obtained from 26 Oriskany tests drilled during 1943 compared with 6 from the same number of tests in 1942. The combined production of wells drilled to the Oriskany sandstone, which produces most of the State output, has declined gradually since 1935. The total initial daily capacity of the 2 completions in 1943 was only 3,500,000 cubic feet. During the past 15 years over 500 Oriskany wells have been drilled in southern New York, in the following counties: Allegany 155; Steuben 214; Chemung 29; Tompkins 30, and most of the remainder in the short lived Wayne-Dundee field in Schuyler and Yates Counties.

Allegany County had six tests drilled to the Oriskany sandstone in 1943, Steuben nine, Chemung four, and Tompkins four. Four of the wells in Steuben County were over 5,000 feet deep and four in Allegany over 4,600 feet. A well in Schuyler County was drilled to 2,902 feet without finding the Oriskany.

Great interest is being shown in two tests that were being drilled at the close of the year. One is the deepening of the discovery well in the Woodhull Oriskany gas field; the other is at Arcade, Wyoming County. Both will penetrate the entire Silurian series and are expected to reach the Trenton limestone.

Underground storage of natural gas has been practiced in southern Erie County since 1918. Other storage areas now in use are in Chatauqua County, where the Medina formation serves as a reservoir, and the Oriskany gas field in Schuyler County. A deep well in Greenwood, Steuben County, and another in Wirt, Allegany County are also being used.

No production figures for New York in 1943 were reported.

North Dakota.—Commercial gas production in North Dakota comes from the small portion of the Cedar Creek field, which lies in Bowman County near the Montana boundary. Wilson M. Laird, State geologist, North Dakota Geological Survey, reports that gas has been found in other counties but is not produced in commercial quantities. No new developments were reported in 1943. Only 6 out of 14 wells were producing during the year. The gas comes from the Eagle sand of the Pierre shale at a depth of about 1,200 feet.

Production was 177,067,000 cubic feet in 1943 compared with 121,955,000 cubic feet in 1942.

Ohio.—Information relative to natural-gas developments in Ohio during 1943 has been supplied by Kenneth Cottingham, chief geologist, Ohio Fuel Gas Co.

Efforts to find production during the year were disappointing. Only 8 more completions were recorded in 1943 than in 1942, but the number of dry holes increased 35, thus reducing the number of successful wells; 11 fewer oil and 16 fewer gas wells were completed. The loss in number of gas wells was somewhat compensated by a decided improvement in the average initial production, 913 thousand cubic feet per well in 1943 compared with 668 in 1942. Wells in the Oriskany sand had the highest initial volume, averaging 1,392 thousand cubic feet per well daily. Those in the Clinton sand averaged 1,237 and those in the Newburg (next in volume) 661 thousand cubic feet. Productive sands and number of gas completions were: Clinton 276, Berea 89, Shallow 57, Oriskany 17, Ohio shale 12, and Newburg 4.

No noteworthy discoveries were made during the year. New territory was limited to about 30 small pools averaging approximately 300 acres each found in 17 counties of eastern Ohio. Most of these pools were considered discoveries rather than extensions to proved acreage, to which they were usually adjacent. Six were from the Berea sand, one from the Newburg, three from Shallow sands, and the remainder from the Clinton. There was no new development in western Ohio, where the Trenton sand predominates.

New Clinton wells proved 1,200 additional acres in Lorain County, 1,000 in Wayne and Holmes, 1,000 in Muskingum, 700 in Tuscarawas, and 700 in Stark. A number of unusually large Clinton wells were drilled in Lorain County, initial production being as high as 13, 12, and 7 million cubic feet. The largest Clinton well of the year was in Muskingum County, completed at a depth of 4,031 feet. Its initial production was 14,364 thousand cubic feet and its initial rock pressure 1,160 pounds. A well with an initial open flow of 7,500 thousand cubic feet drilled to the Clinton sand in Galia County was outstanding because it was unusually large for that area. Depth of the productive sand varied from 2,400 feet in Lorain County to 4,850 feet in Tuscarawas County. The deepest Clinton test was dry. It was drilled in Mahoning County to a depth of 6,059 feet.

The only area where Oriskany drilling predominated was in the northern part of the Cambridge field in Guernsey County, where production was found at a depth of about 3,400 feet. Fourteen gas wells and two dry holes enlarged the proved territory there by about 2,500 acres.

Drilling in the Berea sand was scattered. The most successful pool was in Meigs County, where 12 gas wells and 2 dry holes added about 1,000 acres to the proved territory. The sand in that area is about 1,650 feet deep. The initial flow of the largest well was slightly over 1 million cubic feet a day. Athens and Morgan Counties led in the number of wells drilled to the Berea formation.

The deepest well drilled in 1943 was in Meigs County. It was dry in all formations and finally abandoned at a depth of 7,466 feet.

Twenty-nine counties had gas completions in 1943 compared with 30 in 1942. Morgan County ranked first in number of completions in both years. The highest-ranking counties and the number of wells drilled were as follows: Morgan 53; Medina 38; Muskingum 35, Lorain 29; Athens 27; Holmes 26; Meigs 26; Stark 25; Ashland 22; Perry 22; Guernsey 20; and Washington 20.

No information regarding the production of natural gas in 1943 is as yet available.

Oklahoma.—There were 112 gas completions reported in Oklahoma in 1943 compared with 102 in 1942. Although about twice as many wildcat wells were completed for gas as in 1942, no notable discoveries were made during the year. These discoveries were in the following counties: Hughes, 5; Comanche, Jackson, Okfuskee, and Payne, 3 each; and Greer, McIntosh, Pawnee, Pittsburg, Sequoyah, and Stephens, 1 each.

Elmer Capshaw, gas engineer, Oklahoma Corporation Commission, has supplied the following information relative to natural-gas developments in Oklahoma during 1943. A number of small gas areas were equipped to produce by plugging back depleted oil wells to gas-bearing sands. Failing supplies and the scarcity of new sources of production resulted in more careful utilization of available output and increased efforts to reduce waste. Gas companies connected lines to a number of producing oil properties to use the casinghead gas that might otherwise have been blown to the air.

Gas reserves were drawn upon heavily in 1943, and in the Chickasha-Cement area they may be depleted in 6 or 7 years unless new gas-producing sands are discovered. It is estimated that reserves in the

Hugoton field in Oklahoma and Kansas total about 20 trillion cubic feet of gas, which, at the present rate of withdrawals, will last 30 or 40 years.

Gas was stored in small amounts in the Oklahoma City field in 1943 and in larger quantities in the Osage County field just outside of Tulsa.

Gas production in the State during the year increased about 8 percent over the 1942 record and totaled 297,771 million cubic feet. Gas wells produced 160,456 million (54 percent) and oil wells 137,315 million (46 percent). Of the 1942 total, gas wells produced 125,468 million cubic feet (45 percent) and oil wells 151,064 million (55 percent). These figures indicate a 28-percent increase in dry-gas output in 1943 and a 9-percent decrease in wet gas.

There was a tendency during the year to increase the price of gas at the wells whenever allowed by the Office of Price Administration.

Pennsylvania.—J. G. Montgomery, Jr., vice president, United Natural Gas Co., has supplied information relative to natural-gas developments in Pennsylvania during 1943. The shallow gas fields continued to supply the major part of the natural gas produced in the State during the year.

A total of 770 shallow-sand wells was drilled in 1943, of which 579 (75 percent) produced gas. The majority of these were in known gas areas. Twenty-five had initial open flows of over a million cubic feet per day. Their county locations were: Greene and Westmoreland 4 each, Fayette and Clearfield 3 each, Allegheny, Armstrong, Warren, and Washington 2 each, and Forest, Jefferson, and Clarion 1 each.

A few large-volume wells were drilled in the Armbrust pool discovered in 1941 in Westmoreland County. The area had 2,200 acres proved in 1942, but its limits are now fairly well defined by a number of unproductive tests.

No important discoveries were made during the year, although the ratio of exploratory drilling increased materially. A pool was opened in the Venango sand in Warren County; its limits have not as yet been established. Four of the completions had an average initial production of over a million cubic feet a day, with a rock pressure of only 85 pounds per square inch. A new pool in the Big Injun sand was discovered in Fayette County. Three completions had an average initial production of about 1,170,000 cubic feet a day and a rock pressure of 675 pounds per square inch.

Deep drilling met with little success in 1943. Only one of three wells drilled in what is thought to be a southern extension of the Summit pool in Fayette County found a very small flow of gas. The original discovery well in the pool was deepened and additional production found in a limestone that is probably part of the Upper Silurian series. Three deep wells were drilled to the Oriskany sand in Potter County and one in Tioga County. In Potter County one test was dry, one encountered gas with much salt water, and one was completed as a small gas well. In Tioga County a well drilled between the Sabinsville and Tioga gas pools found the Oriskany sand unproductive.

Tests drilled in McKean, Crawford, Mercer, Beaver, and Westmoreland Counties were not encouraging. A well in Mercer County encountered a small volume of gas in the Lockport dolomite and is being deepened. One well in Westmoreland County drilled to the Oriskany sand was abandoned at 9,024 feet, and a second was abandoned when the key Tully limestone was penetrated twice with a vertical separation of 753 feet. Complex formations and faulting make deep drilling in Pennsylvania difficult and unusually hazardous.

No figures are available for shallow-gas production in Pennsylvania in 1943, but it is estimated that it was close to the maximum rate. Many of the large companies are building up reserves by storing gas in old fields instead of closing in some wells in seasons of low demand, as was customary in pre-war years.

Production from the deep Potter-Tioga County field continued the decline begun in 1939. Output has fallen 93 percent from 30 billion cubic feet in 1939 to 2 billion in 1943.

South Dakota.—A deep gas test drilled to the Dakota sands in Potter County, S. Dak., just east of the Missouri River, was reported in 1943. It had a daily initial flow of 86,400 cubic feet of gas, but production was accompanied by water. Several million acres are now under lease by major oil companies in North and South Dakota.

According to Ernest A. Hanson, supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo., the only production in the State in 1943 was 6.7 million cubic feet produced by the city of Pierre from a water well. The gas is used for heating city and State offices.

Tennessee.—Kendall E. Born, associate geologist, Tennessee Department of Conservation, reports that the only areas in Tennessee producing natural gas commercially in 1943 were Sunbright and vicinity in Morgan County and Jamestown in Fentress County. Approximately 12 wells also supply small volumes of gas for domestic use.

Marketed gas totaled about 18,000,000 cubic feet.

Texas.—Marketed gas production continued upward in 1943 to about 1,320 billion cubic feet, 13 percent above 1942, owing to larger output from gas and condensate wells. The major gas pipe-line systems operated at nearly maximum capacity and in some localities were unable to fully supply total market requirements for brief peak periods.

Incomplete reports indicate that gas-well completions were fewer in 1943 for the second successive year, numbering about 170 compared with 238 in 1942. In the Panhandle the decline was over 50 percent or from 63 in 1942 to 30 in 1943. In West Texas, gas completions were 11 in 1942 and only 8 in 1943. Increases in 1943 over 1942 were reported only in the Lower Gulf Coast and Southwest Texas districts.

In East Texas, condensate fields were discovered at Appleby, Nacogdoches County (Travis Peak formation), and at Stewards Mill, Freestone County (Woodbine sand). The large Carthage field, Panola County, had important extensions to the north, east, and west which establish it as one of the greatest gas reserves in the United States.

Five gas discoveries were reported in North Central Texas as follows: Eastland County one, Palo Pinto two, Shackleford one, and Stevens one. All new gas production was from the Caddo, Strawn, and Marble Falls formations of Pennsylvanian age.

In the Upper Gulf Coast, three dry-gas and several condensate fields were opened. The dry-gas discoveries were Citrus Grove in Matagorda County, which is probably a large field, the Menefee and North Louise fields in Wharton County. Among the condensate discoveries were Chesterville, Colorado County, and Jackson Pasture, Chambers County. An important new condensate sand was found in the Katy field in Waller County.

Gas discoveries were made in McMullen and Starr Counties (South Texas) and in Bee and Refugio Counties (Lower Gulf Coast).

In West Texas the Turner gas field, Crockett County, was discovered, production being from the Whitehorse sandstone at about 1,900 feet. One wildcat gas completion was reported in Sutton County and one in Pecos County. Consideration is being given to gas injection for pressure maintenance in many West Texas fields as a conservation measure. Detailed study of the Colby, Slaughter, and Goldsmith fields is being carried on, which may develop information applicable to many other fields of similar characteristics. Goldsmith produced 16 billion cubic feet of gas in 1943 and Wasson over 13 billion. Many fields in the district produce 1 to 7 billion cubic feet per year, much of which is blown to the air. Hence it is hoped that both increased recovery of oil and conservation of great volumes of gas may result from an extensive pressure-maintenance program.

Utah.—There was no drilling in Utah during 1943, according to Ernest A. Hanson, supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo.

The gross production of natural gas in the State, all from the Clay Basin field, decreased 11 percent—from 4,390 million cubic feet in 1942 to 3,893 million in 1943. Use in the field was estimated at 18 million cubic feet and losses at 10 million, leaving 3,865 million marketed. Comparative figures for 1942 were: Field use 1 million, losses 5 million, and marketed 4,384 million.

The Farnham dome produced 161 million cubic feet of carbon dioxide, which is not included in the foregoing figures. This gas is used in the manufacture of dry ice.

Virginia.—According to William M. McGill, assistant State geologist, Virginia Conservation Commission, the only natural-gas development reported in Virginia during 1943 was the completion of a well that was begun in 1942 in Lee County near Ewing. Gas was encountered with rather high pressures, but the well was capped at a depth of 3,255 feet. No wells were drilled in the Early Grove gas field which, to date, has furnished the only utilized production of the State, or in Rockingham and Prince William Counties, where some drilling activity was reported during 1941 and 1942.

Natural-gas production totaled 84,000,000 cubic feet in 1943 compared with 98,000,000 in 1942.

West Virginia.—The following information was taken from a report by David B. Reger, consulting geologist, Morgantown, W. Va.

About 39,000 acres were added to proved territory in West Virginia during 1943, both in new gas pools and in additions to old ones. Three gas pools discovered before 1943 became definitely active during the year. The output of new wells in all areas was disappointing, and it is doubtful whether additions to production will balance withdrawals.

Leasing of wildcat acreage continued to be active. Forty-two wildcat wells were drilled in 1943, of which 19 were completed as small, commercial gas wells. Comparative figures for 1942 were 53 wells drilled and 27 commercial gas discoveries.

There were 475 gas wells drilled during the year with total daily open-flow capacity of 454,735,000 cubic feet compared with 536 in 1942 and total daily open flow of 1,228,501,000 cubic feet. These figures indicate declines of 11 percent in the number of wells drilled and 63 percent in daily production. The average daily production per well was 957,337 cubic feet in 1943—58 percent less than the average of 2,270,406 cubic feet reported in 1942.

Fifty-seven old wells were deepened during the year, of which 49 were productive. They added 11,484,000 cubic feet of gas to daily productive capacity.

The direct cause of the slump in average well capacity was a sharp decline in completions in the Charleston gas field where wells producing from the Oriskany sand are usually large. There were 203 wells drilled in the field in 1942—only 80 in 1943. Other sources report that approximately half the gas production of West Virginia in 1942 was withdrawn from the Charleston deep field. In 1943 the field's output declined about 30 percent, but the area is expected to produce significant volumes of gas for a number of years.

Three of the seven wells drilled to the Newburg sand produced gas in commercial quantities. None reached the Clinton formation.

A number of promising gas pools have been developed in the Big Lime or Greenbrier sand in the southwestern part of the State. The formation is only 50 to 100 feet thick in the northern part and is generally unproductive, but it is productive farther south, where it thickens and is found at greater depths. The wells react to acid injection, and it is expected that great quantities of gas will be recovered. Initial flow ranges up to 13,000,000 cubic feet a day.

Jackson, Kanawha, and Putnam Counties were the most active in both 1942 and 1943. Counties of greatest development and the number of wells drilled were: Jackson 61, Kanawha 59, Putnam 48, Clay 47, Upshur 42, Lincoln 36, Boone 34, Gilmer 28, and Calhoun 20. Lincoln County with 10 wells and Lewis with 7 led in the number of wells deepened.

Some of the large gas companies are drilling input wells for gas storage in depleted fields in the northern part of the State, principally in Lewis County. The practice of storing a reserve supply close to areas of heavy consumption has increased in importance in recent years.

It is expected that the new pipe line from Texas will furnish about 175,000,000 cubic feet of gas daily to relieve present shortages.

Natural-gas production in West Virginia is estimated at 210,000,000,000 cubic feet in 1943, a 2-percent decline from the 215,193,000,000 reported in 1942.

Wyoming.—Only five gas completions were reported in Wyoming during 1943, all in the Baxter Basin field. Their total initial production was 18,960,240 cubic feet. The largest well ever reported in the Big Piney area found an initial flow of 40 million cubic feet, but it was killed with mud and was not counted as a gas completion. Several other Big Piney wells have had open flows exceeding 100,000 cubic feet. The occurrences of gas in the field are erratic, and pressures are as high as 480 pounds. There is no pipe-line outlet for the gas, which is remote from markets.

Gross production in the State in 1943 was 48,476 million cubic feet compared with 46,471 million in 1942. Of the total quantity, 13,992 million cubic feet were recycled or used for repressuring, 1,090 million were used in the field, and 1,474 million were lost. These figures indicate a 2-percent decrease in the volume of gas used for repressuring and recycling and a 22-percent decrease in the volume used in the field, but a 106-percent increase in losses, caused by an estimated waste of about 1 billion cubic feet of sour gas in the new Tensleep oil pool at Elk Basin. Without that item, losses would probably have decreased. The largest repressuring and recycling operations were in the Lance Creek field, where 5,501 million cubic feet of gas were returned to the sand (5 percent below the 1942 figure); the Salt Creek field, with a return of 5,797 million cubic feet (6 percent below the 1942 figure); and the Wertz field with 1,394 million cubic feet (19 percent above the 1942 record). Repressuring was practiced in the same eight fields as in 1942.

There were 23,298 million cubic feet of gas treated to produce 31,645 thousand gallons of gasoline in 1943, a gain of less than 1 percent in the volume of gas treated and a 5-percent decrease in the quantity of gasoline extracted. Salt Creek, Lance Creek, and Big Sand Draw furnished 96 percent of the total amount of gas processed in both 1942 and 1943.

Marketed production totaled 31,920 million cubic feet in 1943 compared with 30,029 million in 1942. The Sherard field was added to the number of areas from which gas was sold, making 33 fields in 1943. The areas of greatest production were: Baxter Basin with 8,159 million cubic feet, Big Sand Draw 6,128, Lance Creek 2,048, Little Buffalo Basin 2,017, and Salt Creek 2,966. These five fields furnished 67 percent of the total marketed production in Wyoming in 1943 and 66 percent in 1942.

The above information was furnished by Ernest A. Hanson, supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo.

CONSUMPTION

The importance of natural gas as a fuel for wartime industries and in army encampments and Federal housing projects was well established in 1942. Total consumption reached an all-time high of 3,044,773 million cubic feet (9 percent above the 1941 peak of 2,805,192 million cubic feet) and was over twice the total volume consumed in 1917 and 1918 during the last war. Domestic and commercial use increased 16 percent and total industrial 7 percent in contrast with 1941, when the expansion in gas markets was almost entirely in the industrial classification.

Consumption expanded in all the States in 1942 except Washington, where natural gas is no longer used owing to exhaustion of the supply. Texas held first place, followed by Louisiana, California, and Oklahoma. Ohio produced only 31 percent of the State requirements and ranked first in imports from other States in both 1941 and 1942.

The average value of natural gas at points of consumption rose from 22.1 cents in 1941 to 22.7 cents in 1942. This increase was due to a shift in volume to high-priced gas. The average value of most of the major classes of consumption either declined or remained the same as in 1941, indicating that the trend in rates at which gas is sold was not upward.

Natural gas consumed in the United States, 1938–42

Year	Domestic and commercial consumption							
	Consumers (thousands) [1]			Billions of cubic feet			Average number of M cubic feet used per domestic and commercial consumer	Average value at points of consumption per M cubic feet (cents)
	Domestic	Commercial	Total	Domestic	Commercial	Total

[1] Includes natural gas piped from Canada.

[2] Small amount of gas consumed in Tennessee included with Virginia; separate figures not available.

Treated for natural gasoline.—Natural-gasoline plants processed 2,864,400 million cubic feet of natural gas in 1942—4 percent more than the 2,763,300 million processed in 1941. The ratio to total natural-gas consumption was 94 in 1942 compared with 99 in 1941. California registered a decline in the volume of gas treated for the fourth consecutive year. Colorado, Kentucky, Michigan, and New York were the only other States recording decreases. Louisiana was outstanding with a 29-percent increase, influenced by operation of the large Cotton Valley cycle plant which was active only a few months of 1941. The average yield of natural gasoline, including cycle products, was 0.95 gallon per thousand cubic feet of gas processed in 1942 compared with 0.97 gallon in 1941. An average recovery of 1.22 gallons of the lighter products was recorded in 1942 compared with 1.23 gallons in 1941.

Natural gas treated at natural-gasoline plants in the United States, 1938–42, by States, in millions of cubic feet

State	1938	1939	1940	1941	1942

Domestic and commercial.—Inadequate supplies of fuel oil and coal were among important factors reflected in the natural-gas industry in 1942 by a 13-percent gain in domestic and 27-percent gain in commercial consumption.

Domestic consumption totaled 498,537 million cubic feet valued at $352,520,000 in 1942 compared with 442,067 million cubic feet valued at $318,093,000 in 1941. Gains in both the number of domestic consumers and the total quantity consumed were registered in all States using natural gas except Montana, which had 1,540 fewer consumers. Commercial consumption totaled 183,603 million cubic feet valued at $80,189,000 in 1942 compared with 144,844 million cubic feet valued at $68,398,000 in 1941. Factors contributing to the increase in commercial consumption were the use of gas in many Army and Navy training stations and permanent bases and the increased use of restaurants and other commercial eating places by the civilian population because of rationed foods in homes and migration to places of employment in war industry. Decreased commercial consumption was reported in Mississippi and Missouri. All other States registered gains.

The average value of gas used by domestic consumers was 70.7

Domestic and commercial consumption of natural gas in the United States in 1942, by States[1]

[1] Includes natural gas used with manufactured gas.

[2] Maryland includes District of Columbia and Virginia.

[3] Utah includes North Dakota and South Dakota.

cents per thousand cubic feet in 1942, 1.3 cents less than in 1941. The average value of gas used by commercial consumers was 43.7 cents in 1942, 3.5 cents less than in 1941.

The average domestic consumer used 49,191 cubic feet of gas in 1942 compared with 45,433 in 1941.

Field.—Twenty-four percent (721,063 million cubic feet) of the total consumption of natural gas was used in the field in 1942—5 percent above the 1941 figure of 686,158 million cubic feet. Drilling was reduced because of shortages in manpower and materials; hence this gain was probably due to a more extensive use of gas lift in oil fields in a few States. There was an indicated decline of 0.2 cent per thousand cubic feet in the average value of gas used in the field in 1942, caused largely by a 10-percent increase in field consumption in Texas, where gas is relatively cheap.

Carbon-black manufacture.—A 3-percent decline from the 1941 carbon-black output, together with a further increase in the proportion of high-yield furnace blacks produced in 1942, caused a decrease in the amount of gas burned at carbon-black plants. A total of 335,533 million cubic feet was used—8 percent less than the 365,377 million used in 1941. The average value increased 0.2 cent over the 1941 figure to 1.3 cents a thousand cubic feet. The total value was $4,338,000 compared with $4,135,000 in 1941. California and New Mexico were added in 1942 to the list of States in which gas is burned in carbon-black manufacture.

Petroleum refineries.—Natural gas furnished 24 percent of the B. t. u. requirements of petroleum refineries in 1942 compared with 18 percent in 1941. The industry used 201,670 million cubic feet in 1942—36 percent over the 148,127 million used in 1941. Texas, California, and Louisiana were the largest consumers in both years. California displaced Louisiana as second in rank in 1942. The urgent demand for fuel oil for other war purposes caused large-scale conversions from oil to gas fuel at refineries in both Texas and California.

Electric public-utility power plants.—Electric public-utility power plants used 238,736 million cubic feet of gas in 1942, a 16-percent gain over the 205,156 million used in 1941. The figures as reported by the Federal Power Commission include a small percentage of manufactured gas. States registering sharp gains over 1941 records were: Georgia 115 percent, Minnesota 91, Indiana 67, Arizona 62, Colorado 51, Oklahoma 28, and Texas 26. States showing sharp decreases were: Pennsylvania 64 percent, Wyoming 50, Alabama 24, Tennessee 20, and Mississippi 14. Texas, Louisiana, and Kansas recorded the largest amounts of this class of consumption. The region of greatest increase was the south Atlantic, with a 114-percent gain over the 1941 record. The east south central area, with a 19-percent decline, was the region of greatest decrease. The west south central region led in the volume of gas consumed, with 132,040 million cubic feet—18 percent over the 1941 figure and 55 percent of the 1942 total.

Portland-cement plants.—Natural gas consumed at portland-cement plants totaled 64,540 million cubic feet in 1942—19 percent over the amount required in 1941. This gain was due to increased output of portland cement rather than to substitution of gas for fuel oil, as plants using the latter converted to coal wherever possible. In the winter of 1942–43 gas deliveries to several plants, particularly in the Kansas-Missouri district, were curtailed because of local shortages in supply. Conversions to coal and oil reduced the demand for natural gas in 1943.

Other industrial.—Gas used at electric public-utility power plants, as reported by the Federal Power Commission, includes some manufactured gas impossible to segregate. The natural gas used at such plants is therefore included with "other" industrial in the 1942 figures.

Heavy loads for war industries and allied plants in 1942 contributed to a continuation of the increase in "other" industrial consumption, which has been uninterrupted since 1938. A total of 1,039,827 million cubic feet was used during the year compared with 964,441 used in 1941. The gain was general, except in California, Tennessee, Kentucky, and Ohio, where small declines were reported as a result of restricted gas supplies and conversions to oil and coal.

The average value of gas used at petroleum refineries, electric public-utility plants, and portland-cement plants and for "other" industrial purposes remained unchanged at 17.1 cents a thousand cubic feet. The total value in 1942 was $223,535,000; in 1941, $199,419,000.

Mixed gas.—The quantity of natural gas used with manufactured gas increased 17 percent in 1942 to 77,259 million cubic feet from 65,979 million in 1941. Increases were indicated in all States using mixed gas. Illinois, the largest consumer, gained 6 percent and New York, second in rank, 18 percent. In general, the unit value of high-priced domestic and commercial gas decreased, while that of lower-priced industrial gas increased, resulting in a lower average value for all gas of 83.0 cents a thousand cubic feet in 1942 compared with 86.3 cents in 1941. The total value was $64,093,000 in 1942; $56,952,000 in 1941.

INTERSTATE SHIPMENTS

Interstate shipments, which have been expanding since 1938, increased 13 percent over the 1941 record and totaled 919,969 million cubic feet in 1942. All "exporting" States reported increases except Mississippi, Missouri, New York, Utah, and Virginia, none of which is an important supplier to outside areas. Oklahoma gained 64 percent over the volume reported in 1941, Colorado 54 percent, New Mexico 26 percent, and Texas 14 percent. Texas again held first place in the quantity transported (supplying 32 percent of the total), Louisiana was second with 22 percent, and West Virginia ranked third with 16 percent. Louisiana exported 46 percent, West Virginia 66 percent, and Texas 25 percent of the marketed State production.

PIPE-LINE DEVELOPMENTS

At the beginning of the war, existing lines were generally adequate for the transportation of natural gas for current markets. Hence in 1942 few major additions were made to the gas-pipe-line system of the country. Guided by the allocation program of the War Production Board for critical steel and equipment, emphasis was first placed upon construction of oil pipe lines, for which there was a most urgent need. By 1943 the rapid growth in natural-gas demand from war industries and other consumers overtaxed the transmission facilities in several areas, notably in western Pennsylvania, Ohio, western Missouri, and southern California. To avoid shortages that would hinder the war program in these districts, the Federal Power Commission authorized the construction of several large gas lines and numerous extensions and loops with materials released by the War Production Board.

The outstanding project of the year was a line from a point near Corpus Christi, Tex., to Charleston, W. Va., to carry Texas gas to eastern markets. Strong opposition was encountered from interests in gas-producing States involved; but the Federal Power Commission finally issued a certificate of convenience to build, with the provision that the work be started before February 1944 and the line be ready for use by the winter of 1944–45. Construction was begun the first week of December on the Cumberland River northwest of Nashville, Tenn.

Another project to supplement the gas supply from eastern fields was completed in 1943. It consisted of 120 miles of 20-inch line running from the system of the Panhandle Eastern Pipe Line Co. near Maumee, Ohio, to the lines of the East Ohio Gas Co., which supply the industrial areas near Cleveland and Akron. A supply of 50 million cubic feet per day of gas from the Southwest is assured by this connection. To provide capacity to meet increasing demands, the Panhandle Eastern Pipe Line Co. added over 200 miles of 22- to 26-inch pipe to its transmission system in eight loops and installed 24,600 hp. of new compressor-station equipment.

The construction by the Cities Service Transmission & Chemical Co. of 235 miles of 26-inch line from the Oklahoma-Panhandle area of the Hugoton field to Blackwell, Okla., was almost completed in December, and the line was placed in service early in 1944.

Among a number of minor extensions and loops added to existing lines in 1943 were: A 60-mile line of 8-inch pipe between Muskegon, Mich., and the Reed City field; 35 miles of 16- and 12-inch loops from a point north of the Cayuga field to the vicinity of Alma, Tex.; and 35 miles of 12-inch line from the Lula field, Coal County, Okla., to Holdenville.

An application was filed to build a 1,500-mile line from Texas and Louisiana gas fields to transport gas to New York City for wholesale distribution. No official action was taken on the proposal during the year. An application for permission to build a line from the Texas Panhandle to Milwaukee, Wis., was withdrawn in 1943 as currently impractical.

NATURAL GASOLINE

AND LIQUEFIED PETROLEUM GASES[1][2]

NATURAL GASOLINE

SUMMARY

The products of the natural-gasoline industry were in great demand in 1943 at rising prices. Output increased 6 percent over 1942 to 3,703,518 thousand gallons, and total value at the plants was 21 percent higher at $147,000,000. The outstanding gain was in the production of liquefied petroleum gases, as the output of natural gasoline continued to decline in 1943, and cycle products gained comparatively little.

A strong market throughout 1943 is indicated by the Mid-Continent spot price for 26–70 grade natural gasoline, which began the year at 3.88 cents per gallon and rose to 4.75 cents at the close to average 4.13 cents as compared with 3.22 in 1942. The average values of all light products, as reported to the Bureau of Mines, were higher in 1943 than in 1942.

Total stocks declined less than 4 million gallons in 1943, reversing a small increase in 1942. Gains in stocks of cycle products and liquefied petroleum gases, chiefly at refineries, were more than balanced by a reduction of 27 million gallons in natural-gasoline stocks.

Exports have declined during the war period to low levels. The principal movements for 1941, 1942, and 1943 are summarized in this chapter, as this information was omitted after 1940 owing to war restrictions.

---

[1] Data for 1943 are preliminary; detailed statistics with final revisions will be released later.
[2] In this report the term "billion" is equivalent to 1,000,000,000.

[7] Estimated.

PRICES AND MARKET CONDITIONS

After recovering from a low of 2.25 cents per gallon in March 1942 to reach 3.88 cents in December, the Mid-Continent spot price for 26–70 grade natural gasoline remained constant until August 24, 1943. Then upward adjustments were made until a price of 4.75 cents was established on October 8, 1943, and held through the end of the year.

The price ceiling set by the Office of Price Administration on this grade of natural in Oklahoma has been 4.875 cents per gallon f. o. b. plants since February 1942; hence the spot price has closely approached the ceiling level for the first time. Special products, such as isobutane, which are required for the synthetic rubber and aviation-gasoline programs, were exempted from price restrictions to encourage increased output.

The average value at plants of natural gasoline and cycle products (partly estimated) increased sharply in 1943 to 4.5 cents per gallon from 3.8 cents in 1942, and approached the average spot motor-fuel (Oklahoma 72–74 octane) price (see fig. 1).

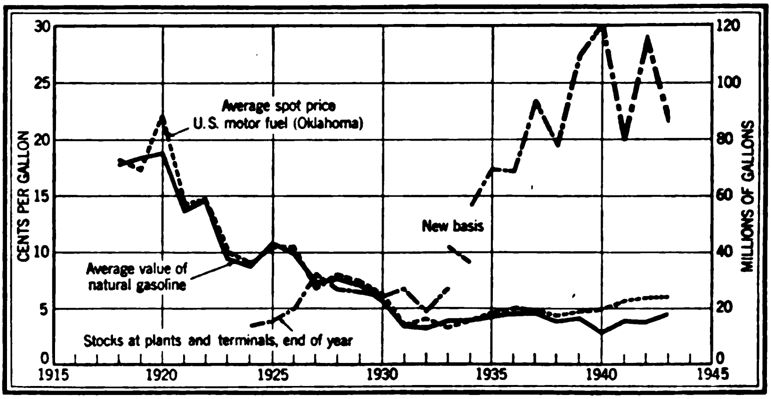

FIGURE 1.—Trends in average value of natural gasoline, spot price of gasoline, and stocks of natural gasoline, 1918–43.

Prices to blenders of Mid-Continent natural gasoline, grade 26–70, with dates of price changes in 1943 and monthly and yearly average, in cents per gallon

		Sept. 4	4.13–4.38		
April: Average	3.88	Sept. 7	4.13	Average: 1943	4.13
		Sept. 11	4.13–4.38	1942	3.22
May: Average	3.88	Sept. 14	4.25–4.63		
		Sept. 15	4.25–4.38		
June: Average	3.88	Sept. 16	4.25		
		Sept. 28	4.50		
		Average	4.29		

The higher average value of natural in 1943 resulted chiefly from firmer market conditions in the important Texas and Louisiana producing district. Large gains in output from this area for which lower than average prices at the plants were obtained have tended in recent years to depress the national average value of natural gasoline relative to the Oklahoma motor-fuel price.

PRODUCTION

Trends in total output.—Production of natural gasoline and cycle products (except L. P. G.) in 1943 was slightly less than in 1942, but crude petroleum output increased 8 percent to a new record, as figure 2 indicates. Since 1939 the volume of natural-gasoline output has changed little, as sharp gains have been recorded in cycle products and liquefied petroleum gases. These data record the effects upon production of growing cycle-plant operations; the installation and use of fractionating facilities at natural-gasoline plants; and, as a minor factor, the practice followed by some companies of crediting plant output with products separated at refineries from unfractionated material received from plants.

Total liquid production by the industry (natural gasoline, cycle products, and L. P. G.) was 3,703.5 million gallons in 1943, 6 percent above 1942. Monthly output was stable during the first half of 1943 at a rate comparable with the fourth quarter of 1942. Several new plants, particularly two large cycle plants in Texas, contributed to a higher rate of production in the latter months of 1943. The fourth-quarter average was almost 800 thousand gallons per day above that of the first quarter.

[1] Subject to revision.

crease from 87,445 thousand gallons in 1942 to 110,139 thousand in 1943. The total output of light products was moderately higher in all principal producing fields except Santa Fe Springs and Long Beach, which declined 6 and 4 percent, respectively. Kettleman Hills produced 143 million gallons, of which 96 million were reported as natural gasoline and 47 million as liquefied gases.

Louisiana.—Total production at natural-gasoline and cycle plants was only 3 percent larger in 1943 than in 1942, a small gain compared with other recent years. Output of natural gasoline dropped 27 percent, but cycle products and liquefied petroleum gases rose 7 and 70

percent, respectively, continuing recent trends. Production in 1944 will be affected by the addition of the cycle plant at Erath, which began to operate in April. Its reported capacity is over 20 million gallons of light products per month.

Oklahoma.—Light-products output declined further in 1943 to 422.2 million gallons from 445.1 in 1942. A small gain in liquefied gases (6.4 million gallons) was accompanied by a material loss (29.3 million gallons) in natural-gasoline production. The total production in the Seminole and Osage districts increased, but Oklahoma City and the rest of the State produced 13 percent less in 1943 than in 1942.

Texas.—Production of 1,670.1 million gallons of light products in 1943 exceeded 1942 by 7 percent to set a new record. As in 1942, the output of natural gasoline declined (5 percent), but increases were reported in cycle products (4 percent) and liquefied gases (33 percent). A tendency to separate larger percentages of liquefied gases is evident at cycle plants as well as at natural-gasoline plants.

A large gain in output was again recorded in the Gulf Coast, where cycle plant-operations continue to expand. New plants of very large capacity in the Katy field, Fort Bend County, North Houston, Harris County, and Lake Creek, Montgomery County, augmented the 1943 supply. Production from East Texas and the Panhandle increased slightly, but output in other districts dropped.

Other States.—Illinois was conspicuous among other important producing States with an increase of 32 percent in light products in 1943, most of which was attributable to liquefied gases formerly wasted. Arkansas continued to process more of its surplus gas, with consequent growth in recovery of liquid hydrocarbons (31 percent) and a small amount of sulfur. New Mexico output fell 9 percent, according to reports, and West Virginia 3 percent, influenced by declining gas production from its leading field (Charleston).

POST-WAR PROSPECTS

The natural-gasoline industry depends generally for its raw materials on oil and gas producers and for its market on petroleum refiners. As its sources of supply have been relatively stable and secure, its habitually volatile course has been dominated by the needs and policies of refiners.

To forecast the probable status of the natural-gasoline industry in the years immediately following the war it is most important, therefore, to consider the magnitude of refinery demand for its several products and the prices that may be anticipated. Recent developments in refining, notably catalytic cracking, have augmented the supply of light products from crude petroleum. These are readily absorbed at present, chiefly by aviation gasoline, synthetic rubber, and special naphthas for varied purposes. Should these war activities be sharply curtailed without a compensating increase in civilian demand, refiners might for an appreciable period reduce drastically their takings of the products derived from natural gas.

This possibility is cause for concern among leaders in the natural-gasoline industry, some of whom are seeking means of minimizing their dependence on refineries. To this end, the following have been mentioned: An increase in production of finished products at field plants to be marketed independently, cooperative processing of liquids from groups of plants, cooperative marketing, and development of new products and markets.

The position of cycle plants particularly is strengthened by their ability to produce in quantity some finished products (chiefly motor fuel) more economically than do refineries. Therefore, if markets for unfinished "natural" products are curtailed, with attendant distress prices, cycle plants within their limited field probably could compete successfully with refineries for a share of the trade in finished products. Most of the smaller, independent, natural-gasoline plants may be forced to alter their past trade practices in order to survive.

The past 2 years have brought an immense increase in understanding by industry and the public of the value of natural gas and its components. The great potential benefits that could flow from this enlightenment may be realized through improved practices in natural-gas use and processing in oil fields. Gasoline plants may become primarily a profitable means of increasing the recovery of petroleum in many fields. To accomplish this on a broad scale, effective unitization of fields must be facilitated by law, and the usual contractual obligations between producers and plant operators will change fundamentally. Changes of this character would be accelerated by a tight supply situation in petroleum and, conversely, would be retarded by an abundant supply.

From the long-term point of view, expanding markets for this industry appear assured. Opportunities for growth are numerous and diverse, but other uses than motor fuel normally require only a minor part of total output.

DEMAND AND MOVEMENTS

The demand for all light products, including liquefied refinery gas (sold for fuel) and benzol, increased in 1943 to 3,979,038 thousand gallons from 3,827,040 thousand in 1942.

Use of natural gasoline declined, as did sales of liquefied refinery gases for fuel. The major increase was in use of liquefied petroleum gases at refineries and for fuel outside the industry. Increased refinery demand for cycle condensate developed because of the great utility of this product in expanding aviation-gasoline production. As a result, jobbers distributed less condensate in 1943. Of the total demand for light products, refineries represented 65 percent in 1943 and 62 percent in 1942.

Refinery utilization.—The importance of natural gasoline and allied products to refinery-gasoline production has increased notably during the war period. In 1943 these materials composed 10.3 percent of the total gasoline output of refineries compared with 9.6 percent in 1942.

The adjacent table shows that expansion of significant proportions in refinery use of these products is limited to the Texas-Louisiana-Arkansas region and Illinois-Indiana. These are the areas in which rapid strides in light-products production have recently been made. Therefore, a strong tendency is evident for refineries to absorb locally the increments to light-product output, of which a small fraction only is transported long distances for refinery utilization.

"Direct" sales.—The quantity of natural gasoline and cycle condensate available to jobbers and others for outside consumption was less in 1943 than in 1942, probably influenced by the urgency of re-

Distribution of natural gasoline and allied products in the United States, 1942–43, by months, in thousands of gallons

---

[1] Subject to revision.

finery demand for these products. Sales of liquefied petroleum gases to distributors for fuel, however, increased a comparable amount, so total sales of light products through these trade outlets did not change greatly in 1943 from 1942.

Percentage of natural gasoline and allied products in refinery gasoline in the United States, 1939–43, by districts

Year	East Coast	Appalachian	Indiana, Illinois, Kentucky	Oklahoma, Kansas, Missouri	Texas Inland	Texas Gulf Coast	Louisiana Gulf Coast	Arkansas and Louisiana Inland	Rocky Mountain	California	Total
1939	2.7	1.4	4.1	7.8	14.3	3.5	2.1	5.0	4.7	18.0	6.6
1940	2.0	1.6	4.5	8.0	16.6	4.4	1.7	3.3	4.5	15.7	6.6
1941	2.3	1.9	5.3	6.6	17.6	5.6	3.7	6.1	4.4	16.1	7.1
1942 [1]	1.4	2.1	5.8	6.3	16.0	13.9	13.1	11.6	4.8	16.7	9.6
1943 [1] [2]	1.1	1.9	6.0	8.6	21.2	14.2	18.3	12.9	4.0	15.0	10.3

[1] Not comparable with prior years because relatively more liquefied petroleum gas is included.

[2] Subject to revision.

Exports.—Publication of separate export data for natural gasoline and allied products was discontinued after the review of 1940, when 71,526 thousand gallons were shipped to foreign countries. During the war this movement has been severely restricted by widespread dislocation of international trade and by the urgent domestic need for these materials in the manufacture of aviation gasoline and other petroleum products required in our war economy.

The following summarizes the principal export items for the latest 3 years, in thousands of gallons. The 1941 total was 53,886, of which 45,074 went to Canada, 4,471 to Mexico, 3,244 to the United Kingdom, and 127 to Portugal. The 1942 total was 57,414, of which 45,407 went to Canada, 4,574 to Mexico, 5,744 to the United Kingdom, and 114 to Portugal. The 1943 total was only 35,154, of which 27,828 went to Canada, 6,122 to Mexico, and 54 to Portugal.

STOCKS

Total stocks of light products originating at natural-gasoline and cycle plants (194,544 thousand gallons on January 1, 1943) increased to a peak of 229,404 on March 31 and subsequently declined to end the year at 190,722. After the first quarter, refinery demand expanded more rapidly than production of these products and was the chief cause of the reversal in stock trend.

Refinery stocks gained 23 million gallons in 1943, and those at plants and terminals decreased 27 million. Following an abrupt decline in 1942, California stocks increased 12 million gallons in 1943. The largest net withdrawal from stocks occurred in Texas and Oklahoma.

Stocks of natural gasoline declined 27 million gallons (17 percent) during 1943, cycle products increased 2 million (13 percent), and liquefied petroleum gases increased 21 million (90 percent). These trends in stocks have persisted for over 2 years. Natural-gasoline stocks have declined since August 1940 when they totaled 323,484 thousand gallons. Most of the large stock increase of L. P. G. in 1943 was accumulated at refineries.

Stocks of natural gasoline and allied products in the United States in 1943, by months, in thousands of gallons [1]

[1] Liquefied refinery gases have been omitted due to the difficulty of segregating stocks for fuel from those for other uses.

TECHNOLOGIC DEVELOPMENTS

Cycling plants.—Two large cycle plants were completed in Texas in 1943; one in California and one in Louisiana began operations early in 1944. Louisiana cycle plants processed about 71 billion cubic feet of natural gas in 1943, with an average yield of liquid products of over 2 gallons per thousand cubic feet. In Texas about 520 billion cubic feet were cycled, yielding 1.1 gallons of liquid hydrocarbons per thousand.

The demand for raw materials for aviation gasoline and synthetic rubber, particularly butanes, has prompted the installation of more equipment at cycle plants for separating a variety of special products and for increasing the recovery of the lighter fractions.

It has been demonstrated that absorption pressures above 2,000 pounds per square inch and injection pressures above 4,500 pounds are practicable in cycle operations; still higher operating pressures are anticipated in later plants, which will draw upon reservoirs at great depths.

Yields.—The average yield of natural gasoline and cycle products (except L. P. G.) declined in 1942 to 0.95 gallon per thousand cubic feet from 0.97 in 1941. Yields declined in nine States, including Texas, Oklahoma, and Louisiana. The total yield of light products per thousand cubic feet declined also from 1.23 in 1941 to 1.22 in 1942. In 1943 the estimated recovery of natural and cycle products continued to decline to 0.93, but the total of all products increased to 1.28, reflecting the emphasis placed upon production of lighter fractions.

Production by processes.—The number of operating gasoline plants continued to decline in 1942, a net loss of 15 being reported. Seventeen compression plants ceased production, chiefly in Illinois and Oklahoma, and 8 came "on stream" in other States. A reduction of 13 absorption-type plants in Texas, West Virginia, and other States was partly offset by the addition of 8 in Oklahoma and Illinois. Some of these changes are doubtless the result of conversion of plants from one type to another. Six new cycle plants began operating in 1942, the same number as was added in 1941.

Natural gasoline and allied products produced in the United States in 1942, by States and by methods of manufacture [1]

[1] Figures for 1943 not yet available.
[2] Includes 16 plants manufacturing liquefied petroleum gases.
[3] Includes combination of absorption process with compression and charcoal processes.
[4] Includes 162 plants manufacturing liquefied petroleum gases.
[5] Includes 13 plants manufacturing liquefied petroleum gases.
[6] Drip gasoline.

The proportion of total liquid production at plants contributed by the several methods in 1942 was as follows: Absorption 74 percent, compression almost 6 percent, cycle 20 percent, and charcoal 0.08 percent. Comparable figures for 1939, based upon production of natural gasoline and cycle condensate only, were: Absorption almost 88 percent, compression (including a small cycle output) 12 percent, and charcoal 0.3 percent.

Vapor pressures.—The average vapor pressure of natural gasoline produced east of California was 21.2 pounds in 1943 and 20.5 in 1942.

Technical trends.—In response to greatly enlarged demands for isobutane, isopentane, and butylene, emphasis was placed on adjusting processing equipment, particularly at large plants, to separate these products or mixtures containing a concentration of them. Plant operations were adapted more closely than ever before to refinery requirements in the interest of maximum efficiency.

Concentrated research effort is continuously producing new techniques and products and new applications for products that have been in commercial use for years. Hence rapid change characterizes many phases of the industry.

LIQUEFIED PETROLEUM GASES

The rate of expansion in sales of liquefied petroleum gases shrank further in 1943, when delivereies of 675,233,000 gallons were only 15 percent above the 1942 total of 585,440,000, compared with increases of 27 percent in 1942 and 48 percent in 1941. Adverse market factors, evident in 1941 and 1942—such as inadequate transportation, shortage of equipment for handling and use, and diversion of increasing quantities for consumption as raw material principally for the manufacture of rubber and high-octane motor fuel—were intensified further in 1943 and prevented distributors from supplying the potential demand in full.

Sales of liquefied petroleum gases in the United States, 1936–43, in thousands of gallons

Year	Butane	Propane	Butane-propane mixtures	Pentane	Total	
					Quantity	Percent of increase over preceding year
1936	40, 200	36, 502	27, 375	2, 575	106, 652	38. 8
1937	45, 399	46, 474	46, 694	2, 833	141, 400	32. 6
1938	52, 768	54, 130	56, 050	2, 253	165, 201	16. 8
1939	71, 351	79, 323	69, 020	3, 886	223, 580	35. 3
1940	77, 056	109, 216	123, 348	3, 836	313, 456	40. 2
1941	112, 244	126, 969	219, 252	4, 387	462, 852	47. 7

[1] Subject to revision.

The respective percentage increases for the principal uses of liquefied petroleum gases varied widely in 1943 compared with 1942. Sales of liquefied petroleum gases for industrial fuel made a greater percentage gain in 1943 than in 1942, but increases for other uses in 1943 (except the minor "all other uses") were below the 1942 rate. Deliveries of liquefied petroleum gases to industrial plants increased 31 percent in 1943 (149,429,000 gallons in 1943 compared with 114,132,000 in 1942) or double the 16-percent gain reported for 1942. The volume of liquefied petroleum gases credited to gas-manufacturing companies (37,519,000 gallons in 1943) was 20 percent above the 1942 total of 31,366,000 gallons—an increment that compares with a 24-percent expansion in 1942. The annual growth in sales of liquefied petroleum gases for domestic use has contracted sharply from a 65-percent gain in 1941 to 36 percent in 1942 and only 13 percent in 1943, owing to supply, equipment, and transportation difficulties. Reported deliveries of liquefied petroleum gases for domestic fuel were 339,380,000 gallons in 1943 against 299,559,000 in 1942. Limited supplies and restrictions in some areas are reflected in the smaller increase in use of liquefied petroleum gases as fuel for internal-combustion engines—87,834,000 gallons in 1943 compared with 82,456,000 in 1942—a 7-percent gain in contrast with a 23-percent expansion in 1942 over 1941. Purchases by chemical plants of liquefied petroleum gases for raw material—55,356,000 gallons in 1943—were only 4 percent above 1942 requirements and compare with a 20-percent gain in this particular demand recorded for 1942.

The percentage shares of the different gases making up total sales of liquefied petroleum gases changed somewhat in 1943 compared with 1942. Liquefied gases reported as butane dropped from 22 percent of the total in 1942 to 21 percent in 1943, as relatively more butane was diverted for raw material to manufacturers of motor fuel and rubber. The propane item for 1943 increased to 32 percent of total sales compared with 26 percent in 1942, a gain reflecting a shift from butane and butane-propane mixtures to propane as an industrial fuel. The rise in the propane proportion of total sales of liquefied petroleum gases was counterbalanced by a similar percentage loss for butane-propane mixtures, as "mixtures" dropped from 52 percent of 1942 deliveries to 46 percent in 1943. Pentane made up less than 1 percent of the 1943 total or about the same proportion as in recent years.

The rising demand for butane for use as raw material is indicated in the declining rate of increase in sales for fuel purposes. Deliveries of butane in 1943—140,122,000 gallons—were 9 percent above the 1942 total of 128,560,000—a gain compared with increments of 15 percent in 1942 and 46 percent in 1941. Equipment for handling butane was not restricted to industrial and chemical plants and established gas-manufacturing companies; consequently sales of butane to such establishments gained in 1943 over 1942. Domestic users could not obtain new equipment for the consumption of butane, and its diversion for use as motor fuel was greatly restricted, so deliveries of butane under these two headings declined in 1943. Gas companies using butane as "stand-by" gas purchased 21,829,000 gallons of butane in 1943, a 76-percent gain over the 1942 quantity of 12,419,000 gallons. It is believed that part of this rise in the use of butane reflects the effort of gas companies to supply communities expanding under war conditions. The use of butane as industrial fuel, which comprises about 40 percent of the total, increased 11 percent from 50,495,000 gallons in 1942 to 56,143,000 in 1943. Chemical plants do not use relatively large quantities of butane as raw material; however, their purchases of 7,972,000 gallons in 1943 were 52 percent above the 1942 total. The use of butane as motor fuel has declined from 18,799,000 gallons in 1941 to 14,870,000 in 1942 and to 9,895,000 in 1943.

A shift to propane for fuel purposes to release butane for raw material is evident in a 45-percent increase in propane sales in 1943—218,273,000 gallons in 1943 and 150,511,000 in 1942—compared with a 19-percent expansion in 1942 over 1941. The totals for all principal uses of propane were larger in 1943 than in 1942, except purchases by chemical companies, which declined. Propane is still predominantly a domestic fuel; however, the proportion of total deliveries reported for domestic use has dropped from 77 percent of the total in 1941 to 75 percent in 1942 and down to 57 percent in 1943. The declining rate of growth in the use of propane for domestic purposes under adverse war conditions is indicated in another way, namely, the smaller percentage gains in sales in recent years—42 percent in 1941, 16 percent in 1942, and 10 percent in 1943. Gas companies do not buy relatively large quantities of propane; however, their purchases increased from 4,957,000 gallons in 1942 to 8,117,000 in 1943—a 64-percent gain contrasted with a 26-percent decline in 1942 compared with 1941 requirements. Propane used as an industrial fuel increased by nearly threefold in 1943 as manufacturers turned to this more available gas in place of butane. Deliveries of propane to industrial plants (73,698,000 gallons in 1943) were 258 percent above the 1942 total of 20,601,000 gallons. Furthermore, the volume of propane reported sold as industrial fuel was above the butane total for the first time in 1943. The quantity of propane used as raw material by chemical plants is not currently important, and the total declined to 4,455,000 gallons in 1943 compared with 5,850,000 gallons in 1942. Increasing sales of propane for internal-combustion-engine fuel has been reported in recent years as the supply of butane has been shifted to other uses. Propane credited as motor fuel has expanded from 1,631,000 gallons in 1941 to 3,112,000 in 1942 and to 4,592,000 in 1943.

Sales of butane-propane mixtures (312,683,000 gallons in 1943) were only slightly above the 1942 total of 301,917,000 gallons. The annual percentage expansion in butane-propane deliveries, similarly to butane, has diminished noticeably in recent years, shrinking from a 78-percent gain in 1941 over 1940 to a 38-percent gain in 1942 and down to an increment of only 4 percent in 1943. Sales of butane mixtures for domestic use increased by 21 percent from 140,516,000 gallons in 1942 to 169,818,000 in 1943. Butane-propane mixtures, like propane, are predominantly domestic fuels; however, the proportion of the total reported for domestic use is expanding for "mixtures," but for propane relatively smaller quantities of the total are going for household consumption. Forty percent of the butane-propane mixtures were delivered for domestic fuel in 1941, 47 percent in 1942, and 54 percent in 1943. Gas-manufacturing companies bought substantially more butane and propane in 1943 but less of the "mixtures," the quantity of the latter declining by 46 percent from 13,961,000 gallons in 1942 to 7,532,000 in 1943. The strong industrial turn to propane for fuel under present conditions is the opposite from the pronounced drop in deliveries of butane-propane mixtures for this purpose, the quantity shrinking by 55 percent from 43,011,000 gallons in 1942 to 19,474,000 in 1943. Large amounts of butane-propane mixtures are used as raw material by chemical plants; however, their requirements have remained fairly constant for several years—39,243,000 gallons in 1941, 38,325,000 in 1942, and 39,584,000 in 1943. As supplies of butane have tightened because of diversion to other channels, the use of butane-propane mixtures for internal-combustion-engine fuel has mounted steadily; the 1943 total of 73,344,000 gallons is 14 percent above the 1942 demand of 64,470,000 gallons.

Sales of pentane, which are relatively unimportant in volume, declined 7 percent from 4,452,000 gallons in 1942 to 4,155,000 in 1943. Most of the pentane is delivered to chemical plants for use as raw material—the quantity declined from 3,607,000 gallons in 1942 to 3,345,000 in 1943. Some pentane is consumed as domestic fuel; however, the total has diminished from 1,128,000 gallons in 1941 to 766,000 in 1942 and to 637,000 in 1943.

Unusual factors under the stress of war conditions have forced some changes in the proportions of the various gases sold for principal uses. Butane, which made up about 16 percent of the domestic demand item in 1940, has gradually decreased to a 13-percent share of the total in 1943. Propane as a domestic fuel had been replaced by butane-propane mixtures to some extent. Propane delivered as domestic fuel, making up over 50 percent of the total demand in 1940, constituted only 37 percent of the domestic-use item in 1943, but "mixtures" have expanded from one-third of the domestic total in 1940 to one half in 1943. Purchases of butane by gas companies dropped from 54 percent of their requirements in 1940 to 40 percent in 1942.

Sales of liquefied petroleum gases in the United States, 1942–43, by uses, methods of transportation, and regional distribution, in thousands of gallons

[1] Subject to revision.

However, this trend was reversed in 1943, when the proportion of butane in gas companies' purchases jumped to 58 percent. The propane share in the liquefied petroleum gases credited to gas companies also followed a trend similar to that of butane, dropping from 26 percent of the total in 1940 to 16 percent in 1942 and then rising to 22 percent in 1943. Sales of butane-propane mixtures to gas companies followed a reverse pattern from that of butane and propane, increasing from 21 percent of total requirements in 1940 to 45 percent in 1942 and then shrinking to 20 percent of the gas-company item in 1943, as this industry turned strongly to butane and propane for "stand-by" gas.

Butane, with its higher B. t. u. content, is the better fuel for industrial use, but manufacturers have had to turn to propane under current conditions. Butane constituted about 47 percent of the liquefied-petroleum-gas requirements of manufacturing plants in 1940 and 1941, 44 percent in 1942, and 38 percent of the total in 1943. The propane share in the industrial-fuel total has fluctuated irregularly from 47 percent in 1940 to 17 percent in 1941 and 18 percent in 1942, followed by a strong upward turn to 49 percent of the total for 1943, as manufacturers bought more than three times as much propane as was reported for 1942. The percentage of butane-propane mixtures in sales of liquefied petroleum gases to industrial establishments, like that for propane, has changed greatly in recent years, constituting 5 percent of the total in 1940, 36 percent in 1941, and 38 percent in 1942, and then dropping to 13 percent of total industrial-fuel requirements in 1943.

Butane-propane mixtures comprise the larger share of liquefied petroleum gases used by chemical plants as raw material, the proportion being about 88 percent of their purchases in 1940 and 1941 and then a shrinkage to 72 percent of the total in 1942 and 1943, as manufacturers of chemicals increased their purchases of butane and propane. Most of the pentane is reported as raw material for chemical plants, and this gas has ranged from 9 percent of the chemical "item" in 1940 to 6 percent in 1943. Butane-propane mixtures are used more than the straight butane and propane as fuel for internal-combustion engines and satisfied about 77 percent of the demand in 1940, 70 percent in 1941, 78 percent in 1942, and 84 percent of the motor-fuel total in 1943. Butane for engine fuel has declined from 28 percent of the 1941 requirements to 11 percent in 1943, as restrictions on its use were put in force. Propane is not used in important volume as a fuel for internal-combustion engines.

The American Gas Association has cooperated with the Bureau of Mines by supplying the following information concerning the distribution of liquefied petroleum gases by manufactured-gas companies in 1943:

> At the end of 1943, liquefied petroleum gas was being delivered through mains to consumers in 219 communities in 32 States by 101 companies supplying 83,320 consumers.
>
> Butane-air gas with heating value ranging from 520 to 1,300 B. t. u. per cubic foot was supplied to 157 communities in 30 States. A mixture of undiluted butane and propane gas with a heating value of 2,800 to 3,000 B. t. u. per cubic foot was supplied to 18 communities in Arizona, California, and New Mexico. Undiluted propane gas with a heating value of 2,550 B. t. u. per cubic foot was supplied to 41 communities in Maryland, Minnesota, Nevada, New Jersey, North Dakota, Virginia, and Wisconsin.

The percentage of bulk shipments of liquefied petroleum gases has tended to increase slightly in recent years as cylinders or other small containers have become difficult to obtain. Liquefied petroleum gases handled in bulk totaled 599,463,000 gallons in 1943 and constituted about 89 percent of all sales compared with 517,504,000 gallons in 1942, or 88 percent of the annual total. Shipments of liquefied petroleum gases in cylinders increased from 67,936,000 gallons in 1942 to 75,770,000 in 1943.

Sales of liquefied petroleum gases in the Pacific coast area (California, Oregon, Washington, Arizona, and Nevada) increased 8 percent from 126,905,000 gallons in 1942 to 136,601,000 in 1943. The 1943 total for the Pacific coast represented 20 percent of the marketed production of liquefied petroleum gases in 1943 compared with a 22-percent share in 1942. Deliveries of liquefied petroleum gases reported for "all other areas" totaled 538,632,000 gallons in 1943, a gain of about 18 percent over the 1942 volume of 458,535,000 gallons.

SUMMARY

The year 1943 was relatively satisfactory for the carbon-black industry. Sales recovered 40 percent from the 1942 slump (occasioned chiefly by severe dislocations in the rubber industry) and expanded rapidly in the fourth quarter of 1943 to levels greatly exceeding production. Hence a sharp decline in stocks of carbon blacks held by producers occurred late in 1943 and continued through the first quarter of 1944. Total production in 1943 was 3 percent above 1942, a decline of 11 percent in output of contact blacks having been offset by a 47-percent gain in the furnace types (see fig. 1).

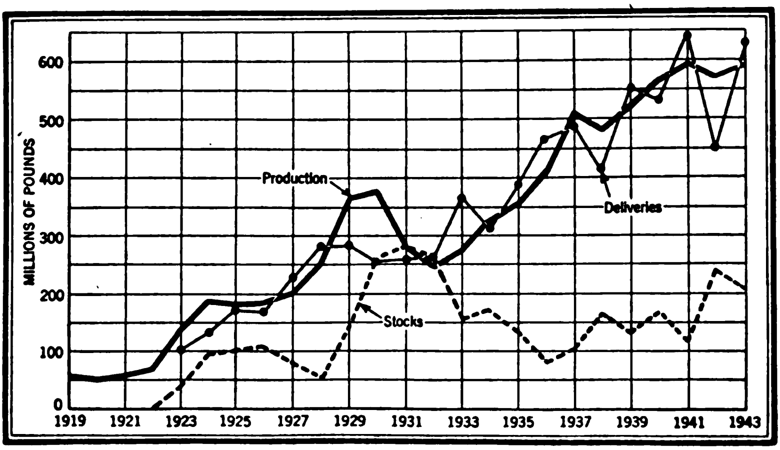

FIGURE 1.—Production, stocks, and deliveries of carbon black, 1919–43.

The rubber trade increased its purchases 60 percent in 1943 to the largest total on record and absorbed 90 percent of all domestic sales compared with 89 percent in 1942. The expanding output of synthetic rubber and products indicates that the rubber companies are emerging from the difficult transition period in 1942 and 1943 and may be expected to utilize larger quantities of carbon black for an extended period.

Exports declined moderately in 1943, as in other years since 1939, and were only 17 percent of total sales.

According to the Office of Price Administration, ceiling prices on all grades of carbon black remained unchanged in 1943.

Salient statistics of carbon black produced from natural gas in the United States, 1939–43

WAR AND POST-WAR SITUATION

The close ties between carbon black and its chief market, the rubber industry, result from common interests of fundamental importance to each. When Japanese conquests compelled the rubber industry to find substitutes for its raw material, and quickly, the carbon-black industry was threatened with loss of its sustaining market unless its product could be adapted to the new conditions. Research by these and other industries into the nature of synthetic rubbers and their processing for varied uses was greatly expanded, with the cooperation of the War Production Board. Knowledge of carbon black in rubber compounds was limited generally to its effects, the specific causes of observed phenomena being unknown; therefore empirical methods were required to guide experiment and development of products. Coordination of the work of the many organizations involved in the program is accomplished through the War Production Board, which promptly disseminates test results and new knowledge to all directly concerned. In one phase of systematic testing, four automotive fleets are maintained to continuously subject tires to severe service tests.

The effects of the program upon carbon-black production are evident in the marked expansion in output of furnace types and of easy-processing channel blacks. The War Production Board estimates total requirements for furnace black of over 300 million pounds in 1944 and 400 million in 1945; and for channel black, about 650 million pounds in 1944 and 675 million in 1945.

It is generally believed that demand for carbon black will be very large for several years after the war, chiefly because a record consumption of rubber is anticipated. A revival of rubber processing abroad should stimulate exports, and the domestic rubber industry looks forward to tremendous tire demands for new vehicles and replacements. The new developments in plastics may create a substantial peacetime market for high-color contact blacks.

The great imponderable with respect to readjustment of the carbon-black industry to post-war conditions relates to the types of blacks which the market will favor; this problem is inseparable from the competitive aspects of natural rubber vs. synthetics in a normal economy. The latter situation involves the interplay of complex and often conflicting forces reflecting variable economic and technical factors and future national and international policies that defy definitive interpretation at present. Simple logic indicates that a great deal of natural rubber will be used in foreign countries and probably in the United States. Its importance relative to synthetics in the post-war world is highly speculative.

PRODUCTION

By States.—Because of a 9-percent reduction in output of the Panhandle and material gains in other States, Texas supplied only 69 percent of the United States total carbon-black production in 1943—the lowest proportion in recent years. Operations in the Texas Panhandle were restricted by a local gas-supply situation, upon which the provisions of Texas law (sweet-gas restrictions) and O. P. A. price ceilings for channel blacks have a bearing. A pipe line has been authorized to bring additional sour gas to channel plants.

War expansion continued in Louisiana, where 1943 output was raised 21 percent to the highest level since 1929. Furnace blacks have become the dominant types produced in Louisiana.

Increased output was reported in all other producing States, the gain in Oklahoma being 29 percent and in the California, Kansas, New Mexico group, 84 percent.

Carbon black produced from natural gas in the United States in 1943, by States and by major producing districts

---

[1] In counting the total number of producers reporting, a producer operating in more than 1 State, district, or county is counted but once.

Methods and yields.—The furnace blacks continued to advance in importance in response to demands of the synthetic rubber program and were 36 percent of total production in 1943, 25 in 1942, and 11 in 1939. Distribution of channel blacks was not controlled by the War Production Board in 1943, but furnace types were under allocation control throughout the year.

The average yield of all carbon blacks increased in 1943 to 1.88 pounds per thousand cubic feet of gas from 1.71 in 1942. All districts reported higher yields except the Texas Panhandle, where the channel process is generally used. The production of easy-processing black at channel plants has increased because of its utility in synthetic rubber processing to about 60 percent of the total channel output. Yields of this grade are about 20 percent lower than yields of the hard and medium grades; hence average yields of channel blacks have declined.

Number and capacity of plants.—At the end of 1943, 54 plants were operating compared with 50 a year earlier. Seven new furnace-type plants began production in the following locations: Kansas one, Louisiana two, Oklahoma one, and Texas three. Three channel plants were shut down or dismantled—one in Oklahoma, and two in Texas.

New facilities expanded the daily capacity of all plants in 1943 to 2,166,713 pounds, or 20 percent above the 1942 total of 1,808,756. The operating rate was about 75 percent of capacity in 1943 and 87 percent in 1942.

Producers.—The list of companies reporting carbon-black production did not change in 1943. Phillips Petroleum Co. is reported to have produced carbon black in 1943 at its Borger (Tex.) refinery by a new process utilizing liquid hydrocarbons as raw materials.

Carbon-black producers of the United States, as of Dec. 31, 1943

[1] Plant, located in both Carson and Hutchinson Counties, counted in Hutchinson County.

DEMAND

Total deliveries.—Total deliveries by producers in 1943 were 629,300,000 pounds, 40 percent more than in 1942. Requirements of all domestic consuming trades increased, but exports declined 9 percent from 1942.

Domestic demand.—Revival of demand, particularly from the rubber industry, caused a 57-percent gain in domestic deliveries by producers in 1943 to 524,388,000 pounds—a new record. Of this quantity, the rubber companies took 90 percent, ink companies 4.5

percent, paint companies 1 percent, and miscellaneous users 4.5 percent (see fig. 2).

Deliveries to the rubber industry in 1943 (473,473,000 pounds) were 60 percent greater than in 1942 and the highest on record. In the last quarter they approached a rate of 600 million pounds per year. Although the rise in demand for furnace blacks in synthetic rubber compounding has been spectacular, great quantities of easy processing channel black are also required. The latter type produces a rubber of tougher wearing qualities than any of the furnace blacks developed thus far. With synthetic rubber slightly more carbon black apparently is used per pound of total output than with natural rubber. Heavier loading with black gives better results for some purposes, and a lower percentage of zinc oxide is generally used. Many articles in varied colors formerly were made of natural rubber without the addition of carbon black. Synthetics, however, are practically useless without the addition of a filler, and their utilization by this section of the rubber trade has created a new outlet for carbon blacks, with a consequent dearth of bright-colored products for the duration of the war.

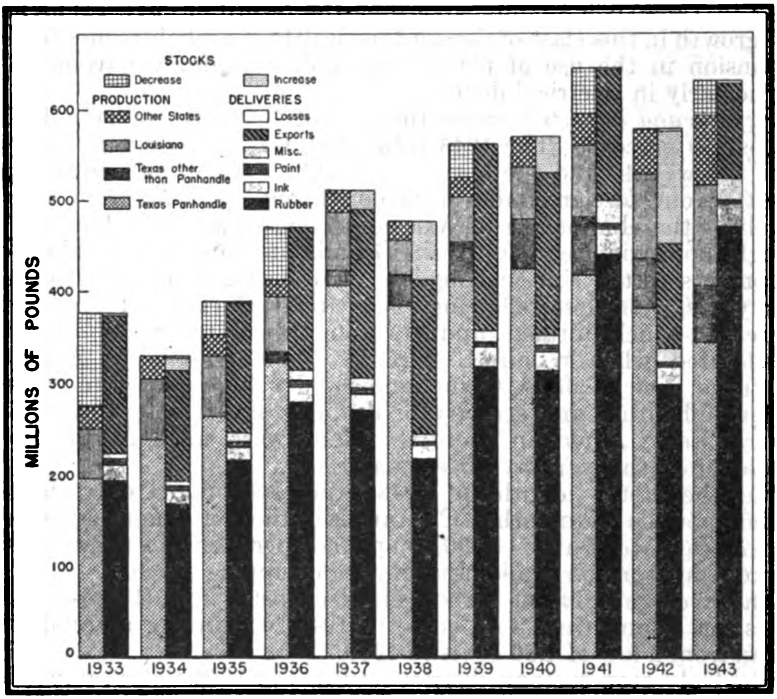

FIGURE 2.—Production and consumption of carbon black, 1933–43. Production in "Texas other than Panhandle" included in "Other States," 1933–35.

Ink companies purchased 23,530,000 pounds in 1943, 22 percent more than in 1942 and approximately equal to the normal pre-war demand of the printing trade. Consumption of newsprint in the United States, according to the Bureau of Foreign and Domestic Commerce, declined from the peak of 3,928,880 tons in 1941 to 3,661,180 in 1943 but was still above consumption in the years before 1940. Over 90 percent of the newsprint is used by newspapers.

Deliveries to paint companies in 1943 (3,945,000 pounds) were 9 percent larger than in 1942 but about 35 percent below the average of recent pre-war years. It is apparent that wartime paint requirements absorb less carbon black than those of civilians in peacetime. Conversion of the automotive industry to the production of military equipment is probably the chief factor in this change.

Sales for miscellaneous purposes in 1943 increased 51 percent over 1942 to 23,440,000 pounds, exceeding the record of 1941. The material growth in this class of demand since 1940 is probably due chiefly to expansion in the use of plastic materials containing carbon black, particularly in electrical devices.

Exports and imports.[1]—Since the peak of 1939 exports have declined almost 50 percent. The 1943 total (104,911,772 pounds) was 9 percent below 1942 and the lowest since 1932. The first major adjustment in our foreign trade in carbon black resulting from the war involved the elimination of Axis-controlled countries, which in 1939 bought approximately 39 percent (79 million pounds) of total exports. Shipments to the United Kingdom have declined consistently in the war years, doubtless reflecting the scarcity of rubber for processing there, for which finished products from the United States have been substituted when required. Declines in shipments to Argentina, Australia, New Zealand, China, and Sweden were related to transportation difficulties and scarcity of rubber. Exports to India and to several Latin American countries which were small factors in this trade before the war have risen materially.

For the first 8 months of 1943 exports averaged only about 7.5 million pounds per month. Clearances in the last 4 months, however, were at the rate of over 11,000,000 pounds per month, suggesting some improvement in the availability of ocean shipping space.

The average value of carbon black exported in 1943 rose to 4.60 cents per pound from 4.52 cents in 1942, continuing a trend which began from a low of 4.36 cents in 1939.

The Galveston customs district returned in 1943 to first importance as an export point, supplanting Michigan after a lapse of 1 year. Several districts reporting heavier traffic in carbon black for export have been added to the table, notably Georgia, which has ranked third in volume handled in 1942 and 1943.

A further sharp rise was reported in imports of "gas black and carbon black" from Canada. In 1943, 208,913 pounds valued at $20,812 were received, compared with 77,870 pounds valued at $7,307 in 1942. Acetylene black, also imported from Canada, amounted to 4,709,482 pounds (value $459,453) in 1943 and 3,840,433 pounds (value $381,204) in 1942.

STOCKS

The accumulation of producers' stocks, which was large in 1942, continued through the first 5 months of 1943. In later months sales increased rapidly to levels above the rate of production and caused heavy drafts upon stocks. The producers' holdings of 242,755,000 pounds at the end of 1942 were reduced to 205,215,000 pounds on December 31, 1943, and the prospect of further growth in demand indicated a need for a higher production rate.

PRICES AND VALUES

The average value of carbon black at the plants in 1943 was reported as 3.41 cents per pound, unchanged from 1942.

Price ceilings promulgated by the Office of Price Administration have remained fixed since January 1942. For important commercial grades they range from 3.3 cents for channel black in bulk to 8.0 cents for some high-modulus furnace blacks.

Ceilings on furnace-type blacks were based upon costs, including that of gas bought under recent contracts at higher rates than formerly prevailed, particularly for supplies to channel plants. Ceilings on channel black were based primarily upon the going market price of the product at the close of 1941. Upon expiration of gas-purchase contracts it was often impracticable to renew them at the old, low rates. Therefore, with a fixed ceiling price on channel plant output, producers have faced the alternative of meeting higher costs without improvement in the sales price of their product or restricting production to that derived from gas still under their control at satisfactory prices.

To alleviate this situation and encourage expansion in channel black production, the War Production Board is requesting (May 1944) of the Office of Price Administration an increase in the ceiling price on channel black. Some downward adjustment in the price ceilings on furnace blacks may also be considered.

Post-war prospects	1240

SUMMARY

Refinery sales of petroleum asphalt (exclusive of road oil) to domestic consumers in the United States were less than 1 percent larger in tonnage in 1943 than in 1942, but because of higher prices they were 11 percent higher in value. As the refinery output was 7 percent larger than in 1942, inventories at the refineries increased 37 percent from December 31, 1942, to December 31, 1943. Exports of petroleum asphalt also increased, but they constituted little more than 1 percent of both domestic and foreign sales. Imports of petroleum and lake asphalt decreased 4 percent but were less than 2 percent of the total new supply in 1943.

Sales of bituminous rock were affected by the decline in road building of the more-stable types, which reduced the sales of paving asphalt from petroleum. On the other hand, sales of gilsonite were increased 26 percent in tonnage by war demands.

NATIVE ASPHALT AND BITUMENS

Bituminous rock.—Decreased road-building activity in 1943, especially by the Federal Government, resulted in a decline in sales of bituminous rock from 935,295 short tons valued at $3,367,279 in 1942 to 835,648 tons valued at $3,096,753 in 1943. Producers in Kentucky and Alabama sold only 185,723 tons valued at $1,093,981 in 1943, compared with 207,324 tons valued at $1,228,748 in 1942. Likewise, west of the Mississippi River producers in Texas and Oklahoma sold 699,572 tons valued at $2,018,822 in 1942 but only 600,545 tons valued at $1,673,689 in 1943. Sales in California also declined during the year. On the other hand, sales of bituminous rock in Missouri, a minor producing State, were larger in 1943 than in 1942. The mining of bituminous rock in Utah was resumed in 1943 after many years of inactivity.

---

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the U. S. Department of Commerce.

Gilsonite and wurtzilite.—In contrast with the decline in sales of bituminous rock, increased demand in both the domestic and foreign market raised producers' sales of gilsonite in Utah from 40,041 short tons valued at $909,311 in 1942 to 50,446 tons valued at $1,188,485 in 1943. The average sales price per ton at the mine or railhead increased from $22.71 to $23.56.

Sales of wurtzilite from Utah increased from 37 short tons valued at $2,852 in 1942 to 41 tons valued at $3,250 in 1943.

Sulfonated bitumen.—Sales of natural sulfonated bitumen from Box Elder County, Utah, were less in 1943 than in 1942.

Exports.—Exports of natural unmanufactured asphalt amounted to 8,941 short tons valued at $231,772 in 1942 and to 34,796 tons valued at $819,355 in 1943. Considerably more natural asphalt was shipped to Australia and New Zealand in 1943 than in 1942, and more was exported to the United Kingdom and to the Caribbean-Gulf of Mexico region.

MANUFACTURED OR PETROLEUM ASPHALT

Production.—Production of asphalt by petroleum refineries in the United States increased 7 percent from 1942. The principal gains were in the East Coast district where completion of the Big Inch pipe line had permitted resumption of normal refining activity, the Oklahoma-Kansas-Missouri district, the Indiana-Illinois-Kentucky-etc. district, and California. In contrast with the general increase, output of asphalt declined in the Texas Gulf Coast district, Louisiana and Arkansas, and the Appalachian district.

Production, receipts, stocks, consumption, transfers, losses, exports, and domestic sales of asphalt (exclusive of road oil) at petroleum refineries in the United States in 1943, by districts, in short tons

District	Production	Receipts from other sources	Stocks		Consumption by companies, transfers, losses, and exports	Sales to domestic consumers
			Dec. 31, 1942	Dec. 31, 1943		
East Coast	1,012,800	118,300	50,000	81,100	51,000	1,049,000
Appalachian	324,800	600	26,400	19,500	46,300	286,000
Indiana, Illinois, Kentucky, etc	1,425,000	233,900	96,700	113,800	173,100	1,468,700
Oklahoma, Kansas, and Missouri	700,100	7,000	39,600	69,300	14,700	662,700
Texas:						
Gulf Coast	435,600		23,800	29,100	68,500	361,800
Inland	410,500	2,500	20,200	32,400	21,000	379,800
Total Texas	846,100	2,500	44,000	61,500	89,500	741,600
Louisiana-Arkansas:						
Louisiana Gulf Coast	483,000	5,000	38,000	54,500	18,600	452,900
Arkansas and Louisiana Inland	356,500	9,100	22,000	28,500	11,700	347,400
Total Louisiana-Arkansas	839,500	14,100	60,000	83,000	30,300	800,300
Rocky Mountain	192,600	113,900	18,500	33,600	19,100	272,300
California	1,415,800	227,100	75,800	101,500		1,617,200
Total United States:						
1943	6,756,700	717,400	411,000	563,300	424,000	6,897,800
1942	6,296,500	1,050,900	604,000	411,000	699,600	6,840,800

Stocks.—Production of petroleum asphalt in 1943 obviously outstripped the increase in demand, as stocks held at refineries rose from 411,000 short tons on December 31, 1942, to 563,300 tons on December 31, 1943. The greatest increases in inventories were in the East Coast district, the Oklahoma-Kansas-Missouri district, California, and the Indiana-Illinois-Kentucky-etc. district. Only in the Appalachian district did a decrease in stocks run counter to the general trend.

Sales.—Sales of petroleum asphalt by refineries to domestic consumers in the United States increased less than 1 percent in quantity but 11 percent in value from 1942 to 1943. The average value at the refinery increased from $10.35 per short ton to $11.43.

Of the total sold, 4 percent was manufactured from foreign petroleum (imported chiefly from Venezuela and Mexico) in 1943 compared with 7 percent in 1942. Although runs of foreign crude oil to stills decreased only 17 percent, sales of petroleum asphalt from this source decreased 40 percent. Of the foreign crude processed, 19 percent (revised figure) was converted into asphalt in 1942 and 15 percent in 1943. East Coast refineries sold 71 percent of the total asphalt made from foreign crude in 1943 compared with 88 percent in 1942. Fully 39 percent of the sales of asphalt made from foreign crude was made by the Gulf Coast refineries of Texas and Louisiana.

Asphalt and asphaltic material (exclusive of road oil) sold at petroleum refineries to domestic consumers in the United States in 1943, by varieties

Total United States	6,840,781	70,815,301	6,897,803	78,862,830

Highway and street construction and airport-runway surfacing used (in the form of paving asphalt, paving flux, cut-back asphalts, and asphalt emulsions) 64 percent of the total asphalt sold to domestic consumers by petroleum refineries in 1942 and 67 percent in 1943. Street and road contracts exceeding $25,000, according to the Engineering News-Record, show a decrease of 57 percent in value—from 530.5 million dollars in 1942 to 227.2 million dollars in 1943—and of 40 percent in indicated volume if the values are adjusted by the Engineering News-Record index of construction costs. The decreases were general over the country but were greatest in the 14 States lying west of the Mississippi River and east of the Rocky Mountains in the 5 States lying between the Ohio River and the Great Lakes, and in the 10 Southeastern States and Louisiana.

Nevertheless, sales of paving asphalt used for high-type surfacing decreased only 7 percent from 1942 to 1943. Government purchases, rather than private contracts, are believed to have sustained sales of paving asphalt.

In contrast with sales of paving asphalt, sales of cut-back asphalts, suitable for surfacing lighter-type highways, increased 23 percent from 1942 to 1943. Sales of rapid-curing cut-backs increased 18 percent in tonnage and of medium-curing cut-backs, 27 percent. The greatest gains were in the Indiana-Illinois-Kentucky-etc. district, the East Coast district, the Oklahoma-Kansas district, the Texas Inland district, the Louisiana Gulf Coast district, and California. On the other hand, sales of cut-back asphalts in the Appalachian, the Texas Gulf Coast, and the Rocky Mountain districts were lower in 1943 than in 1942.

Less emulsified asphalt was sold in 1943 than in 1942. Petroleum refineries sold 118,645 short tons (27,955,076 gallons) valued at $1,481,652 in 1942 and 107,954 tons (25,436,068 gallons) valued at $1,220,177 in 1943; in addition, 86,973,381 gallons valued at $8,996,057 in 1942 and 74,422,435 gallons valued at $6,973,894 in 1943 were sold by major industrial companies that purchased asphalt from petroleum refineries. Accordingly, total known sales of emulsified asphalts and fluxes decreased 13 percent in quantity—from 114,928,457 gallons in 1942 to 99,858,503 gallons in 1943—and 22 percent in value—from $10,477,709 in 1942 to $8,194,071 in 1943.

Roofing manufacture made the second-largest demand for asphalt, absorbing 27 percent of the total sales to domestic consumers in 1942 and 24 percent in 1943. Shipments of prepared roofing reported to the Bureau of the Census decreased 10 percent—from 54,106,000 squares in 1942 to 48,892,000 squares in 1943—and domestic sales of roofing asphalt and roofing flux combined decreased 11 percent—from 1,869,458 short tons in 1942 to 1,670,465 tons in 1943. Except for the Texas Gulf Coast and inland Louisiana and Arkansas, the decrease in sales of roofing asphalt and flux was general.

DISTRIBUTION BY RAIL

The tonnage of asphalt (natural, byproduct, or petroleum) terminated by class I railroads in the United States decreased from 5,971,636 short tons in 1942 to 5,059,518 tons in 1943, according to freight-commodity statistics compiled by the Interstate Commerce Commission. Increased deliveries in the Middle Atlantic and in the South Atlantic States were inadequate to offset the general decline in railroad terminations. The Office of Defense Transportation, by favoring deliveries of asphalt by motor truck within a fairly wide radius of each plant, was largely responsible for the decline in railroad transport of asphalt in 1943.

FOREIGN TRADE

Imports.—Imports of natural asphalt and bitumen into the United States in 1943 totaled 8,142 short tons valued at $221,503 compared with 7,961 tons valued at $136,054 in 1942. Imports of lake asphalt from Trinidad increased from 6,122 tons valued at $79,817 in 1942 to 6,966 tons valued at $202,082 in 1943, but imports of grahamite from Cuba decreased from 1,351 tons valued at $24,741 to 999 tons valued at $17,900.

Imports of solid asphalt increased from 68,638 short tons valued at $309,140 in 1942 to 101,089 tons valued at $567,832 in 1943. Of the 1943 imports, virtually all came from the Netherlands West Indies.

In addition, 255,934 barrels (46,533 tons) valued at $370,606 of liquid petroleum asphalt, including cutbacks and road oil, were imported in 1942 and 51,409 barrels (9,347 tons) valued at $91,001 in 1943. Mexico supplied all the liquid petroleum asphalt imported in 1943.

Exports.—Exports of petroleum asphalt increased 7 percent from 1942 to 1943 but still remained nearly 60 percent below the 1941 level. The principal gains in 1943 were in shipments to Australia and New Zealand, Nigeria and other African war bases, and British India. Exports to North American countries declined, as did shipments to South America, except to Chile and Uruguay. Asphalt exports to Europe, negligible in 1942, virtually reached the vanishing point in 1943.

ROAD OIL

The manufacture and sale of road oil were reported in 1943 chiefly by the Rocky Mountain district and California. What was sold in 1943 as road oil might better have been described as liquid asphalt, as the use of road oil for paving purposes had been officially prohibited. Recommendation No. 45 of the Petroleum Coordinator for War, dated April 24, 1942, which placed asphalt surfacing in the Eastern Seaboard States under control of the Public Roads Administration, did not permit the use of road oil during the emergency; by October 5, 1942, this control and this prohibition were valid over the entire continental United States. Petroleum Directive No. 66, of the Petroleum Administration for War, dated May 22, 1943, defined the types of asphalt permitted to be used for paving purposes or laying dust, and limited these to asphalt cements, cutbacks, and emulsions. After the revocation of Recommendation No. 45, Petroleum Directive No. 72 of the Petroleum Administration for War dated September 9, 1943, continued the restrictions on the delivery or acceptance of road oil for use as a paving material or as a dust palliative. Accordingly, the statistics of road oil for 1943 refer to liquid asphalts having a penetration less than 350 after distillation to 680° F.

Production, receipts, stocks, consumption, transfers, losses, exports, and domestic sales of road oil in the United States in 1943, by districts, in thousands of barrels

POST-WAR PROSPECTS

The prospects of the asphalt industry immediately after the end of the present war seem quite favorable. The cessation of hostilities will find the highways of the United States in comparatively poor condition. Although the highways have been subjected to additional wear through troop movements and freight shipments, little new construction was undertaken during 1942 and 1943 except in the vicinity of camps and cantonments, and maintenance was generally skimped. Undoubtedly a demand will arise at the end of the war to restore the highways to their previous condition; in fact, post-war highway projects to a total value of 1.3 billion dollars have been reported to the Engineering News-Record. These projects in turn should create a demand for paving asphalt, paving flux, cut-back asphalts, and asphalt emulsions.

Moreover, building construction for residential and business purposes, especially that financed by private funds, has lagged during the war. At the end of the war the pent-up demand for small residences and apartments and small business structures should revive building construction. Estimates of the total value of this anticipated construction by the Engineering News-Record range between 2 and 3 billion dollars. Roofing asphalt and flux, waterproofing asphalt and flux, mastic, pipe coatings, and paints and enamels should benefit by any revival of building construction.

SUMMARY

The demand for hydraulic cements declined sharply in 1943 as the construction phase of the war program neared completion and structural activity fell rapidly. Total production of 135,254,054 barrels of hydraulic cements was 27 percent below the record set in 1942, a reduction that resulted from respective decreases of 27 and 29 percent in output of portland cement and of a grouping of all other hydraulic cements (natural, masonry, puzzolan, and hydraulic lime). The portland-cement industry operated at 55 percent, and the "All other" group at 44 percent of productive capacity in 1943. Mill shipments fell 31 percent below the high annual volume of 1942 and totaled 129,478,662 barrels. Demand for portland cement, as gaged by shipments, declined nearly one-third, and for the group of all other hydraulic cements decreased about one-fourth from 1942. As production exceeded shipments by nearly 6 million barrels, stocks of all hydraulic cements at mills on December 31, 1943, advanced to 23,408,972 barrels or 33 percent above the quantity on hand at the close of 1942. During 1943 no adjustments were made in the permitted maximum prices for cement which had been frozen at the levels of March 1 to 15, 1942. The average net mill realization per barrel of portland cement increased 4 cents over 1942 to $1.57 in 1943, whereas that for the "All other hydraulic cements" group dropped 18 cents to $1.28 in 1943.

Although the peak activity of the war construction program reportedly was reached during the July-September quarter of 1942, the long-term trend in production of cement continued upward until February 1943. This extension past the turning point in structural activity resulted from the necessity to rebuild the depleted stocks of cement to the customary operating level as well as to meet the strong demand. In February the steady rise that had started in the middle of 1940 was reversed sharply, and the long-term trend declined at an accelerating rate each month through November. In December the rate of decline lessened slightly, but a sizable proportion of the month's production entered stocks.

Through 1943, monthly output of cement bore little resemblance to the usual seasonal pattern. Peak monthly volume was attained in January, and after a sharp decline in February output was built up at a much less than seasonal rate through May. During June–October production fell in each successive month, whereas customarily there is a slightly rising trend through this period. The rate of decline in November was greater and in December was less than the common seasonal decreases for these months. December output was lower than in any other month of 1943.

[3] Revised figures.
[4] Figures not available for publication.

Demand for cement, as measured by mill shipments, had shown a long-term uptrend through 1941–42 nearly similar to that of production. This uptrend in demand continued beyond the record high structural activity of the third quarter of 1942 and was not interrupted until December 1942. It turned definitely downward in March 1943 at a rate of decline that, although somewhat variable, accelerated rapidly through October. The rate of decrease was eased slightly during November and December. Monthly shipments in 1943 advanced from a January-February level to the peak monthly volume of the year in April. Contrary to the usual seasonal pattern, the monthly movement during April–September fluctuated in a relatively narrow range. The volume fell rapidly through October–December and in December reached the lowest monthly quantity of the year.

The second year of war effected further changes in the location of consumption of cement, and the Southern States became the leading consuming region of continental United States (see fig. 1). Consumption in 1943, as indicated by destinations of shipments of portland cement, slumped from 1942 in each of the socioeconomic regions [1] of the country at varying rates of decline that ranged from 23 percent in the Pacific States to 38 percent in the Northeastern States.

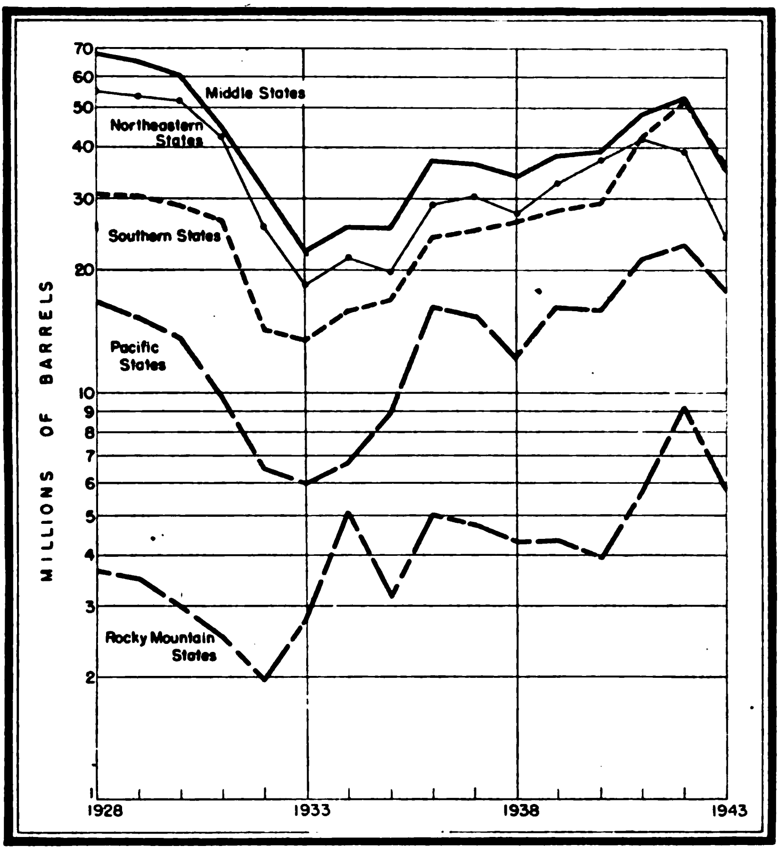

Figure 1.—Trends of indicated consumption of portland cement in continental United States, 1928–43, by regions.

The declines in output and mill shipments of cement in 1943 were less severe than the slump in construction activity, owing to continuation of the uptrend in demand for cement into the beginning of 1943 while structural activity was declining. Total new construction activity in 1943, as estimated upon a value basis by the United States Department of Commerce, was off 42 percent from 1942. Residential building contracts awarded, according to Dodge Corporation data for 37 Eastern States, declined 52 percent, and contracts for all other construction were 63 percent below the corresponding awards in 1942. Contracts for engineering construction, as reported by the Engineering News-Record, fell two-thirds below the 1942 value. The volume of construction that was contracted in 1942 but did not consume cement until in 1943 was indicated by the Portland Cement Association's data on concrete paving contracted and completed. In 1943 contracts were awarded for 71,089,671 square yards, whereas 93,650,221 square yards were completed. Concrete paving completed at airports in 1943 represented slightly more than two-thirds of the total and was only 20 percent below the record area of 1942. Road, street, and alley paving declined 35 percent from the yardage completed in 1942.

---

[1] Bureau of Mines Minerals Yearbook, 1942, p. 1204.

War controls on the cement industries were increased during 1943 and were directed primarily toward conservation of manpower, equipment, fuel, power, and transportation facilities. The general order limiting construction, Conservation Order L-41 of the War Production Board, was amended several times, and major revisions of November 1, 1943, and April 19, 1944, were more restrictive in total effect on new construction than the preceding ones. Regulation of highway construction was removed from the general order on April 19, 1944, and the restrictions were eased slightly under the new control, Conservation Order L-41-e, which permitted the construction of four classes of road or street work without prior authorization. The War Production Board, through its Facilities Committee composed of representatives of several Federal agencies, continued to restrict construction through 1943 to the minimum necessary for essential military and civilian needs. General Limitation Order L-179 [2] on the portland-cement industry was amended on February 16 and March 23, 1943, by removing the ban on assignment of bin space to customers and the restrictions on testing. This order permits, with several exceptions, production only of the general-use, moderate-heat, and high-early-strength types of portland cement. Emergency alternate specifications of the American Society for Testing Materials covering the three permitted types of portland cement were continued throughout 1943. The limitations of the Federal emergency alternate specifications of June 5, 1942, covering the three types of portland cement were incorporated in the regular specifications (SS-C-158a, 191b, 201a, and 201b) by Amendment 1 of August 13, 1943. Preference Rating Order P-56, under which cement producers get priority ratings from the War Production Board to obtain maintenance, repair, operating supplies, and new capital equipment, was amended several times during 1943. Reportedly, it was difficult to obtain items of major plant and quarry equipment.

Car-loading requirements on cement were not changed in the revised regulation, General Order ODT 18A of the Office of Defense Transportation. However, loading requirements on shipments of cement in containers for dealers' warehouse stocks were relaxed on November 1, by Amendment 1 to General Permit ODT 18A-1. As a means of conserving transportation facilities and reducing excessive haulage, all "interzone" rail and truck deliveries greater than 20,000 pounds (about 50 barrels) of bulk or packed general use and moderate-heat (types I and II) portland cements were placed under control September 25 by the War Production Board in Schedule 1 of General

---

[2] Bureau of Mines Minerals Yearbook 1942, p. 1195.

Haulage Conservation Order T-1. The 93 zones set forth in the schedule were consolidated to 73 in the amended forms effective February 1, 1944. Under these regulations, authorization of the War Production Board was required only to make shipments by truck or rail from a point of origin in one zone into another zone; and shipments within a zone, or made entirely by water, or for a distance of 50 miles or less or of other types of portland cement were not subject to the controls. The haulage restrictions on cement were suspended March 10, 1944, because the controls were believed to be discriminatory, inasmuch as portland cement was the only solid commodity so regulated.. During the period that "interzone" shipments were controlled, a number of cement companies used Certificate 93 of July 10, 1943, to Haulage Request TR-2 as a means of accommodating established customers in other zones. Under this provision, the producers were permitted to exchange materials and facilities and the participants in such arrangements were protected from antitrust action. This request (TR-2) continued in effect after Schedule 1 of General Haulage Conservation Order T-1 was suspended and provided a voluntary means of conserving transportation facilities.

The cement-pricing methods[3] of Maximum Price Regulation 224 were continued through 1943. Supplemental Order 53 of the Office of Price Administration, effective September 8, provided a flexible pricing provision. An amendment (No. 4), effective January 11, 1944, clarified methods of pricing sales to exporters and brought the cement regulation (No. 224) in line with the Second Revised Maximum Export Price Regulation on direct export sales. Amendment 5 of January 18, 1944, to the cement order (No. 224) removed the requirement of reporting all sales of cement outside the producer's normal market area to the Office of Price Administration. A maximum increase of 20 cents per barrel in producers' and dealers' prices of general-use, high-early-strength, and other types of portland cement for sales in the northeastern section of the country was allowed in Amendment 6, effective April 20, 1944, to Maximum Price Regulation 224. This price adjustment did not apply to sales of white portland, natural, masonry, or other modified types of cement. Ceiling prices on hydraulic lime in 1943 were unchanged from the March 1942 maximums established by Maximum Price Regulation 188 of August 1, 1942.

Culminating a long period of investigation the Federal Trade Commission, on July 17, 1943, issued an order[4] directing the Cement Institute and 75 member corporations to stop engaging in or continuing any combination to sell cement at prices set by use of the multiple basing-point, delivered-price system or by use of any other plan that results in identical price quotations or prices. The order claimed that the respondents' practices violated the Federal Trade Commission Act and resulted in price discrimination among customers in violation of the Robinson-Patman Act. Some claimed effects of the practices were restraint of competition in the sale and distribution of cement between States, depriving purchasers of the benefits of price competition, maintenance of artificial and monopolistic prices, preventing purchasers from selecting their own means of transporting cement (especially by truck and boat), maintenance of a classification of customers, maintenance of uniform conditions and terms of sale, and hindering the sale of imported cement. The order listed 17 specific practices that are termed unfair and prohibits use of these or any similar means that would accomplish the same ends.

[3] Bureau of Mines Minerals Yearbook 1942, p. 1195.

[4] Federal Trade Commission, In the Matter of Cement Institute, et al., Order to Cease and Desist: Docket 3167, July 17, 1943, 134 pp. and Order.

The respondents filed petitions [5] of appeal on July 28, and the case was certified to the Seventh Circuit Court of Appeals in Chicago. The court granted the producers until March 20, 1944, to file their statement of points and evidence, and after that granted the Federal Trade Commission until June 10, 1944, to submit its review.

Cement producers in all sections of the country reported labor shortages, high rates of labor turn-over, and sharply increased costs of production. Wage-earner employment, according to the Bureau of Labor Statistics, in January 1943 was 115.0 percent of the 1939 monthly average and declined steadily in each month to 87.7 percent in December. As a measure of the increased labor costs resulting from wage increases and overtime rates of pay, the index of wage-earner pay rolls in 1943 was 141.2 compared with 100 in 1939. The monthly indexes (1939 monthly average=100) ranged between 149.9 in January and 127.4 in December. Increases in basic wage rates were reported by some producers in Pennsylvania, West Virginia, Ohio, Illinois, Tennessee, Missouri, and California; the reported increases ranged from 2 to 5½ cents per hour. Labor costs were raised considerably by the overtime rates of pay at the many plants that operated on a 48-hour workweek in place of the former 40-hour week as a means of solving the labor shortage or of holding current labor forces. Fixed production costs per barrel of output, such as capital investment and plant depreciation, mounted rapidly in 1943 as the volume of production fell with the declining demand for cement. Other factors that increased production costs were the rising costs of fuel, supplies, and repair parts.

POST-WAR OUTLOOK

Although the outlook for the cement industry is dismal for the duration of the European War and possibly the Far Eastern War, the post-war prospects are excellent. War restrictions on construction, effective since April 1942, have resulted in a large backlog of deferred civilian and public construction, of which the largest volumes probably are for highways and buildings. By the end of the war, highways will have deteriorated badly and will need extensive repairs and modernization, the extent of which may be gaged by the American Association of State Highway Officials' estimate that, as of July 1943, approximately 7 billion dollars would be required to repair and modernize existing highways in the State systems. The scope of new highway construction is exemplified by the proposed construction, over a period of years, of a system of interregional highways totaling 34,000 miles. All planners agree on the need for new highways and disagree only on the proportional participations of the State and Federal Governments, on the mileage allocations, and on the rates of construction. Forecasts of residential building have unanimity in predicting large annual volumes for a period of years beginning immediately after war restrictions are removed. Farm building also is expected to rise to high levels. Surprisingly, airport paving probably will bulk large in post-war construction because of the greater load requirements necessitated by the increasing size of planes and of other factors that kept airport design in a constant state of flux and have resulted in early obsolescence of airfields. Also, airplane flight strips flanking major highways in all parts of the country are planned. In addition to highways, some other public-works programs under consideration include rural-road improvement, bridge construction, slum clearance, river and harbor improvement, and large dams for flood control and irrigation. The Dodge Corporation estimates that the total physical volume of construction in the 10 years following the present war will be double the relatively low average annual volume of the 1930–39 period and about 5 percent above the relatively high activity in the 1920–29 decade.

[5] Petition to Review and Set Aside Order of the Federal Trade Commission, Cement Institute Against Federal Trade Commission in the United States Circuit Court of Appeals for the Seventh Circuit: Donovan, Leisure, Newton & Lombard (legal firm), 1943, New York, 18 pp.

Petition to Review and Set Aside Order of the Federal Trade Commission, Aetna Portland Cement Co. et al. Against Federal Trade Commission in the United States Circuit Court of Appeals for the Seventh Circuit: Donovan, Leisure, Newton & Lombard (legal firm), 1943, New York, 250 pp.

The eminently favorable prospects for construction activity foretell widespread and large markets for cement in the post-war period. In addition, soil-cement construction is being accepted rapidly and opens extensive new fields for the use of cement.

PORTLAND CEMENT

PRODUCTION, SHIPMENTS, AND STOCKS

As annual production of portland cement represents 99 percent of the total output of all hydraulic cements, the general conditions affecting and the activity of the portland-cement industry during 1943 were the same as those given in the preceding summary.

The 1943 output of portland cement was obtained from 153 active plants in 34 States and Puerto Rico. The leading States, in order of production, were Pennsylvania, California, Texas, Michigan, and Ohio. Production was sharply lower than in 1942 in all Bureau of Mines districts in continental United States; the rates of decline ranged from 11 percent in Colorado-Montana-Utah-Wyoming-Idaho to 44 percent in New York-Maine. In Puerto Rico, however, output in 1943 nearly doubled that in 1942.

Shipments from mills during 1943 were below production in all districts except Michigan, Oregon-Washington, and Puerto Rico, and these excepted districts were the only ones to show lower stocks on December 31, 1943, than on the same date of 1942.

[1] Figures include New Jersey (January to July, inclusive).

Stocks of finished cement at the end of 1942 were usually low but were replenished rapidly nearly to the customary operating level by March 31, 1943, from which they declined to the low for the year on October 31. They were rebuilt to about the usual level at the end of 1943. The increasing range of fluctuation in end-of-month stocks of finished portland cement and clinker from 1940 through 1942 was in sharp contrast to the usual trends in stocks. These wide variations and the return to more normal levels in 1943 are shown in figure 2. At the end of 1943, stocks of finished cement made under emergency alternate specifications may be termed high in the light of possible demand in 1944. The disposal of these stocks in an orderly manner represents the only prospective problem in adjusting the industry to post-war competitive markets for cement made under regular specifications.

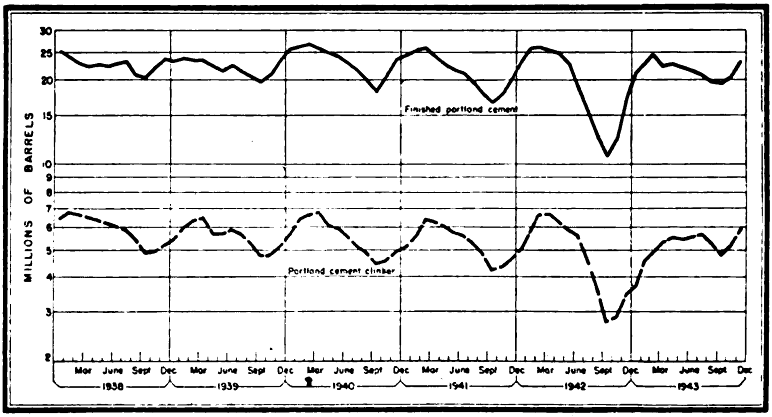

FIGURE 2.—Trends in end-of-month stocks of finished portland cement and portland-cement clinker, 1938–43.

Clinker stocks also were very low at the end of 1942 and were rebuilt more slowly than those of finished cement. They were replenished to an apparently satisfactory level by the end of May. It is noteworthy that stocks of clinker declined in only 3 months—June, September, and October—of 1943 and were highest on December 31.

Stocks of finished portland cement and portland-cement clinker at mills in the United States on December 31, and yearly range in end-of-month stocks, 1939–43

		Dec. 31 (barrels)	Range

[1] Revised figure.

DOMESTIC CONSUMPTION

Indicated consumption of portland cement in 1943 was above 1942 only in Delaware, North Carolina, Wyoming, and Idaho and was lower in all other States and the District of Columbia. The changes in regional consumption are illustrated in figure 1.

Destination of shipments of finished portland cement from mills in the United States, 1941–43, by States

Destination	1941 (barrels)	1942 (barrels)	1943	
			Barrels	Percent of change from 1942
Alabama	2,491,851	3,237,883	2,354,265	−27.3
Arizona [1]	793,838	1,379,825	997,273	−27.7
Arkansas	1,146,712	2,931,890	1,280,188	−56.3
California	16,850,718	17,444,451	13,157,805	−24.6
Colorado	1,520,646	2,204,461	951,031	−56.9
Connecticut [1]	2,379,471	1,996,198	1,094,609	−45.2
Delaware [1]	394,451	348,283	531,444	+52.6
District of Columbia [1]	1,590,499	1,566,360	1,314,305	−16.1
Florida	3,172,179	3,640,849	2,997,035	−17.7
Georgia	2,671,255	2,991,447	2,252,132	−24.7
Idaho	448,380	570,378	726,204	+27.3
Illinois	9,165,894	9,717,134	5,984,967	−38.4
Indiana	5,319,791	6,359,018	3,407,387	−46.4

[1] Shipments by producers to foreign countries and to noncontiguous Territories of the United States (Alaska, Hawaii, Puerto Rico, etc.) including distribution from Puerto Rican mills.

LOCAL SUPPLIES

Local supplies of portland cement listed in the following table do not indicate areas or States in which a definite shortage of cement existed, because parts of any area or State commonly are supplied from mills of a neighboring State within normal shipping range. The total surplus of producing States in 1943 was distributed as follows: 16,136,410 barrels to non-cement-producing States, 5,948,844 barrels to destinations outside continental United States (excluding local consumption of Puerto Rican production), and 36,319 barrels to unspecified destinations.

Estimated surplus or deficiency in local supply of portland cement in cement-producing States, 1942–43, in barrels

[1] Does not include New Jersey for 1943; production and shipments were discontinued July 1942.

TRANSPORTATION

The proportional use of transportation facilities by the portland-cement industry in 1943 changed somewhat from 1942 and was nearly the same as in 1941, the last peacetime year. Railroads transported 83 percent of total cement shipments in 1943 compared with 85 percent in 1942 and 82 percent in 1941. Despite continued gasoline and tire rationing, the percentage moved by truck increased from 13 in 1942 to 15 in 1943. The shrinkage of cement markets under war restrictions and the conversion of many bulk-cement railroad cars to transporting other materials in 1943 undoubtedly were factors in the decreased proportions shipped by rail and the increased proportions moved by truck. The percentage of total shipments moved by boat was slightly higher than in 1942 and slightly lower than in 1941.

The proportions of total shipments moved in cloth and paper containers changed sharply in 1943 from 1942, although the aggregate percentage shipped in containers was unchanged. Paper bags were used for 36 percent of total shipments in 1943 compared with 31 percent in 1942, whereas cloth bags were used for only 22 percent in 1943 compared with 26 percent in 1942. Makers of new cloth and paper bags were limited by the War Production Board in 1943 to the manufacture of only one size of bag—94 pounds net weight—for portland cement. Although the proportion of total shipments moved in bulk was unchanged, the facilities used to transport bulk cement showed marked differences from 1942. The proportions of bulk shipments moved by truck in 1943 increased nearly 3 percent and by rail declined slightly more than 3 percent from the corresponding proportions in 1942.

Shipments of portland cement from mills in the United States, 1941–43, in bulk and in containers, by types of carriers

[1] Includes steel drums and iron and wood barrels.

[2] Includes shipments for Puerto Rico.

[3] Includes cement used at mills by producers as follows—1941: 196,765 barrels; 1942: 181,642 barrels; 1943: 153,337 barrels.

[4] Less than 0.05 percent.

MILL VALUES

The average net mill realization of all portland cement shipped from mills in 1943 advanced to $1.57 per barrel from $1.53 in 1942. Much of this gain in average mill value may be ascribed to the increased proportion of shipments of the relatively higher-valued high-early-strength, white, and oil-well cements, which represented 6 percent of total shipments in 1943 compared with 4 percent in 1942. Another contributing factor was less freight absorption in 1943 owing to the narrowing of cement markets, which were restricted by the haulage conservation orders and by the limitations of the maximum price regulation on sales outside the normal shipping area of a mill. Moreover, the selling prices on some long-term contracts did not expire until late in 1942 or early in 1943 and were below the permitted maximum prices.

The composite wholesale price of portland cement, f. o. b. destination, declined slightly from 1942 according to the Bureau of Labor Statistics index (1926=100), which was 93.8 in 1943 and 94.0 in 1942.

Average mill value per barrel, in bulk, of portland cement in the United States, 1939–43

1939	$1.47	1942	$1.53
1940	1.46	1943	1.57
1941	1.47		

CAPACITY OF PLANTS

The aggregate annual capacity of all portland-cement plants declined about 6¼ million barrels in 1943 from 1942, owing principally to the closing and dismantling of several mills. The new capacity formula set up by the Bureau of Mines for the 1943 canvass also tended to reduce the reported capacities. Data for 1943 include figures on 153 active mills. The over-all rate of operations in 1943 was at 55 percent of total capacity. In general, plant activity was appreciably higher in the Southern States and in States west of the Mississippi River than in the remainder of the country.

Portland-cement-manufacturing capacity of the United States, 1942–43, by producing districts

District	Estimated capacity (barrels)		Percent of capacity utilized	
	1942	1943	1942	1943

[1] Does not include New Jersey for 1943; production was discontinued July 1942.

The distribution of cement plants according to annual capacity differed considerably in 1943 from 1942. The number of plants with capacity under 1,000,000 barrels on December 31, 1943, increased to 44 compared with 37 in 1942, whereas the number in each of the other groups decreased.

The percentage of capacity used in each month of 1943 except in January was lower than in the corresponding month of 1942. The monthly rate of operations in 1943 was highest in January and lowest in December.

Distribution of portland-cement plants in the United States in 1943, according to annual capacity

With completion of a new wet-process mill, the total capacity of wet plants exceeded that of dry plants in 1943 for the first time. As in recent years, the wet-process capacity was utilitzed more fully than the dry-process capacity.

Capacity of portland-cement plants in the United States, 1941-43, by processes

CLINKER PRODUCTION

Production of clinker, the intermediate product of the industry, was 25 percent below 1942. Stocks at mills on December 31, 1943, were at a satisfactory operating level and were 70 percent above the unusually low quantity on hand at the end of 1942.

Production and stocks of portland-cement clinker at mills in the United States in 1943, by months and districts, in thousands of barrels

PRODUCTION ACCORDING TO RAW MATERIALS

Portland-cement plants using cement rock and limestone as raw materials supplied only 22 percent of the total production in 1943 compared with 27 percent in 1942. This decline in relative importance of the cement-rock and limestone mixture may be attributed to the lower activity of mills in the northeastern section of the country where these rocks are the principal raw materials. Mixtures of limestone and clay or shale are the predominant raw materials employed in southern and western mills, and as these mills were relatively more active in 1943 the percentage of total output made from these raw materials increased to 69 from 63 in 1942. The proportion of the 1943 production made from the marl-clay mixture was unchanged and for the slag-limestone mixture declined slightly from 1942.

Production and percentage of total output of portland cement in the United States, 1898–1914, 1926, 1929, 1933, 1935, 1941, 1942, and 1943, according to raw materials

[1] Includes output of 2 plants using oystershells and clay in 1926; 3 plants in 1929, 1933, and 1935; and 4 plants in 1941, 1942, and 1943.

RAW MATERIALS

The tonnages of raw materials required for the 1943 output of finished portland cement are listed in the following table.

Raw materials used in producing portland cement in the United States, 1941–43

	1941	1942	1943
	Short tons	*Short tons*	*Short tons*
Cement rock	12,593,385	13,538,358	8,564,458
Limestone [1]	31,957,951	36,198,156	28,598,436
Marl	1,066,635	903,360	699,456
Clay and shale [2]	4,726,842	5,181,757	4,004,316
Blast-furnace slag	659,201	809,371	544,084
Gypsum	1,035,179	1,248,448	850,660
Sand and sandstone [3]	430,248	567,689	350,941
Iron materials [4]	227,968	252,200	188,096
Miscellaneous [5]	57,844	159,104	38,542
Total	52,755,253	58,858,443	43,838,989
	Pounds	*Pounds*	*Pounds*
Average total weight required per barrel (376 pounds) of finished cement	643	644	657

[1] Includes oystershells.
[2] Includes bentonite, diatomaceous shale, and fuller's earth.
[3] Includes silica and quartz.
[4] Includes iron ore, pyrite cinders and ore, and mill scale.
[5] Includes diatomite, fluorspar, pumicite, flue dust, pitch, red mud and rock, hydrated lime, tufa, cinders calcium chloride, sludge, grinding aids, and air-entraining compound.

FUELS AND POWER

Several kilns in Kansas were converted from gas to coal or oil firing to forestall any prospective fuel shortages. At times in 1943, cement production in some Pacific Northwest plants was curtailed owing to difficulties in obtaining fuel supplies.

Finished portland cement produced and fuel consumed by the portland-cement industry in the United States, 1942–43, by processes

Process	Finished cement produced			Fuel consumed [1]		
	Plants	Barrels of 376 pounds	Percent of total	Coal (short tons)	Oil (barrels of 42 gallons)	Natural gas (cubic feet)
1942						
Wet	[2] 89	95,171,022	52.1	[3] 3,637,571	1,896,044	40,850,105,348
Dry	65	87,610,162	47.9	3,932,516	1,532,975	23,689,722,940

TYPES OF CEMENT

A complete break-down of total production of portland cement in 1943 into the various types is presented in the following table. The general-use and moderate-heat types are combined because separate records are not kept at a number of plants where mill-run cement will pass specifications for both types, and no differential is made in the selling price of either type. In 1943 demand fell for all types of cement except white.

Prepared masonry mortars.—Production of these mixed materials in 1943 from 54 plants totaled 1,993,862 barrels and shipments 1,914,060 barrels, valued at $2,962,367, an average mill realization of $1.55 per barrel. These data are not included in the statistics of this chapter, but the portland cement used in producing the mixtures is included.

Portland cement produced and shipped in the United States, 1939–43, by types

Kind and year	Active plants	Production (barrels)	Shipments		
			Barrels	Value	
				Total	Average
General use and moderate heat (types I and II):[1] 1943	153	123, 490, 667	118, 347, 297	$182,682,614	$1. 54
High-early-strength (type III):					
1939	79	3, 780, 716	3, 693, 460	6, 964, 608	1. 89
1940	88	4, 478, 797	4, 401, 449	8, 243, 315	1. 87
1941	90	6, 063, 638	6, 123, 224	11, 443, 792	1. 87
1942	87	7, 523, 647	7, 065, 700	13, 683, 665	1. 94
1943	95	6, 816, 671	6, 299, 190	12, 040, 467	1. 91
Low-heat (type IV):[1] 1943	4	1, 710, 617	1, 687, 277	2, 316, 755	1. 37
Sulfate-resisting (type V):					
1939	4	38, 279	27, 362	57, 867	2. 11
1940	11	193, 348	200, 090	316, 280	1. 58
1941	9	342, 400	353, 885	544, 767	1. 54
1942	8	79, 835	77, 015	136, 939	1. 78
1943	5	24, 419	20, 697	40, 933	1. 98
Oil-well:					
1939	12	375, 866	375, 027	710, 032	1. 89

1943	22	217, 506	176, 670	320, 838	1. 82

[1] Figures reported separately for the first time in 1943.

[2] Bureau of Mines not at liberty to publish figures separately.

[3] Includes hydroplastic and plastic portland cements, 1939–42, and hydroplastic, plastic, and waterproofed cements in 1943.

NEW DEVELOPMENTS

The outstanding plant development of 1943 was the start of production in the new wet-process plant[6] at Northampton, Pa. Flotation of raw materials is employed so that most types of gray cement may be made from rock of the plant quarry.

In 1943 construction was started on two plants designed to produce Bayer-grade alumina from domestic materials with a byproduct suitable for production of low-alumina cement. One plant (at Harleyville, S. C.) uses a lime-clay sinter and soda-leach process and will begin operating in 1944. The other (at Laramie, Wyo.) employs a lime-anorthosite-soda sinter and soda-leach process and will start producing in 1945.

Rockwood, Nathan C., World's Latest Cement Plant: Rock Products, vol. 46, No. 11, November 1943, pp. 43–81.
Trauffer, W. E., Universal Atlas' New Cement Plant at Northampton: Pit and Quarry, vol. 36, No. 5, November 1943, pp. 65–101.

Concomitant with the slump in demand for portland cement in 1943, producers became interested in utilizing plant equipment to make other materials needed in the war program. Six cement plants (one each in New York, Michigan, Wisconsin, Tennessee, Missouri, and Texas) were converted in part to the production of lime. Seven other plants (four in Pennsylvania, two in New York, and one in Minnesota) were converted partly to the nodulizing of iron-ore fines or sludge or flue dust for blast-furnace feed. Other conversions of cement equipment were for the production of defluorinated phosphate rock (one plant each in Pennsylvania and Illinois), sodium aluminate (one plant in Illinois), process materials for magnesium metal (one plant in Michigan), and flux and pulverized limestone (one plant in Alabama). In addition, the machine shop of a plant in Pennsylvania was converted entirely to production of war materials, and one plant in Michigan produced cement paints.

The findings of a fundamental electron-microscope study of the crystals resulting from the hydration of portland cement compounds and of portland cement were published.[7]

Investigations [8] on additions of eight materials to pastes of different portland-cement clinkers revealed that some materials caused large changes only in the early behavior of the pastes and that few of the substances had appreciable effects on tests at 28 days.

NATURAL, MASONRY (NATURAL), AND PUZZOLAN CEMENTS

Data on the group of hydraulic cements other than portland are presented in the following table. In 1943, producers reported consumption of 24,679 short tons of coal and of gas equivalent to 52 tons of coal.

Natural, masonry (natural), and puzzolan (slag-lime) cements produced, shipped, and in stock at mills in the United States, 1939–43

Year	Production		Shipments		Stock (Dec. 31)
	Active plants	Barrels (376 pounds)	Barrels (376 pounds)	Value	Barrels (376 pounds)
1939	12	2,439,110	2,405,135	$3,361,724	239,938
1940	12	2,534,566	2,514,597	3,386,801	259,868
1941	12	2,875,962	2,926,203	3,967,567	199,365
1942	11	2,560,425	2,508,324	3,668,169	[1] 253,307
1943	10	1,830,266	1,846,803	2,357,112	236,770

[1] Revised figure.

TRENDS IN EMPLOYMENT AND OUTPUT PER MAN[9]

The average number of men employed increased each year from 1938 through 1942, when output of finished cement set a new record.

---

[8] Newman, Edwin S., Blaine, Raymond L., Jumper, Charles S., and Kalousek, George L., Effects of Additions on Cement Clinker Pastes: Nat. Bureau of Standards Jour. Research, vol. 30, No. 4, April 1943, pp. 281–301.

[9] Statistics on employment and output per man presented in this discussion were compiled by D. I. Marsh from records of the Accident Analysis Division, Bureau of Mines.

Compared with 1928, the number of employees and man-hours worked in 1942 was appreciably lower, although the total production was greater. In 1942 a total of 29,768 employees averaged 7.5 hours per shift for 315 days and produced 2.59 barrels per man-hour; in 1928, the estimated total of 35,100 men averaged 9.5 hours per shift for 324 days and produced 1.63 barrels of cement per man-hour. The long-term increase in output per man-hour from 1928 to 1942 indicates the gain in plant efficiency that has resulted largely from mechanization. As would be expected from the continual modernization of plants and the increasing volume of annual production, output per man-hour increased each year from 1938 through 1942.

Employment in the portland-cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1938–42

Year	Employment					Production			Percent of industry represented [1]
	Average number of men	Time employed				Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Man-hours			Per shift	Per hour	
				Average per man per day	Total

[3] Revised.

MILL EMPLOYMENT

The number of men employed in mills represented 79 percent of total employment by the industry in 1942, and as they averaged 323 days of work they supplied 80 percent of the total man-hours.

Mill employees in the portland-cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1938–42

Year	Employment—cement mill only					Production			Percent of industry represented [1]
	Average number of men	Time employed				Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Man-hours			Per shift	Per hour

QUARRY AND CRUSHER EMPLOYMENT

The number of quarry and crusher employees was 17 percent of the total for the industry in 1942, but as they averaged 280 days employment they furnished 16 percent of the total man-hours worked.

Quarry and crusher employees in the portland-cement industry, material (quarry rock and overburden) handled at quarries included in study, and average output of material per man in the United States, 1938–42

Year	Employment—quarry and crusher only					Material handled—quarry rock and overburden				Percent of industry represented[1]
	Average number of men	Time employed				Short tons	Percent of overburden included	Average per man (short tons)		
		Average number of days	Total man-shifts	Man-hours				Per shift	Per hour	
				Average per man per day	Total

HOURS PER DAY

In general, the length of the average working day in the cement industry during 1942 was shorter than in 1941. Slightly less than half of the total employees in 1942 worked an average day of 8 to 9 hours, whereas in 1941 nearly two-thirds of the employees worked an average day of the same length.

Number of men employed in the portland-cement industry in the United States[1] and output per man-hour, 1940–42, classified according to hours of labor per day

Hours per day	1940			1941			1942		
	Men employed		Production per man-hour (barrels)	Men employed		Production per man-hour (barrels)	Men employed		Production per man-hour (barrels)
	Number	Percent of total		Number	Percent of total		Number	Percent of total	
Less than 6	681	2.6	2.44				1,395	4.7	2.77
6 and less than 7	6,282	24.1	2.62	5,872	20.7	2.65	6,043	20.3	2.54
7 and less than 8	4,679	18.0	2.20	4,607	16.2	2.39	8,427	28.3	2.75
8 and less than 9	14,263	54.8	2.37	17,809	62.7	2.60	13,672	45.9	2.50
9 and less than 10	133	.5	2.29	121	.4	2.30	231	.8	2.60

EMPLOYMENT BY DISTRICTS AND STATES

In 1942 the number of employees working at cement plants in the Eastern Pennsylvania-New Jersey-Maryland district and in the State of Pennsylvania exceeded by far the number employed at plants in any other district or State. Although employment in the Eastern Pennsylvania-New Jersey-Maryland district represented 19 percent of the total, output from mills in this district was only 17 percent of total production during 1942. The employment data for 1941 and 1942 are broken down by districts and States in the following tables.

Employment in the portland-cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1941–42, by districts and by States (excluding Puerto Rico)

District and State	Employment					Production			Per-cent of industry represented [1]
	Average number of men	Time employed				Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Man-hours			Per shift	Per hour	
				Average per man per day	Total

[1] Calculated for each year by dividing quantity of finished cement produced at mills included in study by total production in continental United States.

[2] Less than 0.1 percent.

[3] Arkansas, Colorado, Florida, Georgia, Idaho, Indiana, Kentucky, Louisiana, Maine, Maryland, Minnesota, Montana, Nebraska, New Jersey, Oklahoma, Oregon, South Dakota, Utah, Virginia, Washington, West Virginia, Wisconsin, and Wyoming.

FOREIGN TRADE[10]

Imports.—Following the outbreak of war in Europe in 1939, imports of all hydraulic cements declined rapidly to the negligible quantity of 644 barrels in 1942:

Hydraulic cement imported for consumption in the United States, 1938–43

Year	Barrels	Value	Year	Barrels	Value
1938	1,727,411	$1,436,730	1941	43,466	$59,048
1939	1,913,853	1,860,543	1942	644	2,020
1940	538,060	506,191	1943	(1)	(1)

[1] Data not available for publication.

Imports of all hydraulic cements except "white, nonstaining portland cement" in 1941 and 1942, so far as may be published, are listed by country of origin in the following table. Imports of white, nonstaining cement totaled 1,061 barrels valued at $3,784 in 1941 and 304 barrels, $1,201 in 1942.

Roman, portland, and other hydraulic cements imported for consumption in the United States, 1941–42, by countries[1]

[1943 data not available for publication]

Country	1941		1942	
	Barrels	Value	Barrels	Value
Canada	469	$871	281	$695
Japan	14,367	16,078		
Mexico			59	124
United Kingdom[2]	27,569	38,315		
	42,405	55,264	340	819

[1] Excludes "white, nonstaining, and other special cements."
[2] United Kingdom of Great Britain and Northern Ireland.

Exports.—Exports of cement to foreign countries were sharply higher in 1941 than in 1940, but in 1942 the quantity exported declined 57 percent from 1941. In 1942 exports to Latin American countries, the principal export markets for United States cement, fell appreciably. Despite rising consumption in the Latin American countries, exports of United States cement to these markets in the post-war period probably will be below pre-war levels owing to the rapidly increasing self-sufficiency of these countries. However, this loss may be more than offset by the possibility of increased exports to Far Eastern and European markets when peace returns.

Hydraulic cement exported from the United States, 1939–41

[1943 data not available for publication]

Year	Barrels	Value	Percent of total shipments from mills
1939	1,146,339	$2,352,693	0.9
1940	1,667,595	3,294,118	1.3
1941	2,556,234	5,663,037	1.5
1942	1,100,826	2,707,217	.6

---

[1] Data not available for publication.

Shipments of hydraulic cement to noncontiguous Territories of the United States in 1941 were: 254,457 barrels valued at $554,363 to Alaska, 1,074,230 barrels at $1,887,383 to Hawaii, 800,860 barrels at $1,584,195 to Puerto Rico, and 52,369 barrels at $108,547 to the Virgin Islands.

WORLD PRODUCTION

World production of hydraulic cements in 1943 is estimated at 81,000,000 metric tons, a gain of 13 percent over the estimated output in 1942.

Although production in 1943 declined in the United States and Canada, outputs in nearly all other countries of the American continents were appreciably higher than in 1942 owing to greatly increased activity in road, housing, industrial, and public-works construction. The Latin American countries are prospering during the war and the governments of many of them already have embarked on ambitious public-works and housing programs. However, in some of these countries, notably in Brazil, inadequate fuel supplies limited production in 1943.

The changing tide of war in Europe probably resulted in increased output of cement in 1943 as the Allies built new airfields and roads and repaired damage in regained territories, and as the Axis countries rushed fortifications and other military construction. Shortage of transportation facilities and fuel supplies appeared to be the factors determining the rate of operations at most European plants. In general, plants in sections remote from the war fronts, as in eastern Germany, or distant from fuel supplies, as in Denmark, reportedly were operated at relatively low rates. Plants in more favorable locations apparently were operated at or near capacity.

In Asia and Australia production probably advanced over 1942 as the Allies became the attackers, and the Japanese rushed military and other construction to entrench themselves in the conquered areas. Production probably declined in South Africa and increased in the countries of northern Africa.

World production of hydraulic cements, 1938–43, by countries, in metric tons [1]

GENERAL CONDITIONS

Sales of crushed and dimension stone combined (171,343,250 tons) were 13 percent less in 1943 than in 1942 when output attained an all-time high record of 195,884,490 short tons. The total value of sales ($184,320,034) was 10 percent smaller than in 1942. Sales of crushed and broken stone declined because the peak of Government construction had been passed and privately financed construction was very small. Dimension stone sales declined still further from the unusually low levels of 1942 because wartime construction requires very small quantities of building stone. Crushed and broken stone output declined 12 percent in quantity and 9 percent in value, and dimension stone (excluding slate) 38 percent in quantity and 20 percent in value.

The present chapter follows the general plan inaugurated in 1938, whereby the data on dimension stone are separated from those on crushed stone, except in the introductory general tables.

The tables of this report give the quantities sold or used by producers and the values f. o. b. quarries and mills insofar as these figures are obtainable. Stone quarried and used by producers is considered as sold and is included in the statistics of sales. The data, however, do not include stone made into abrasives (such as grindstones) or that used in making lime and cement. These materials are reported in terms of finished products in the Abrasive Materials, Lime, and Cement chapters of this volume. The following tables show the total sales of stone by kinds, uses, and States.

Stone sold or used by producers in the United States, 1939-43, by kinds

[Quantities approximate]

Year	Granite		Basalt and related rocks (trap rock)		Marble		Limestone	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

DIMENSION STONE

The term "dimension stone" is applied to blocks or slabs of natural stone cut to more or less definite shapes and sizes and used principally for the construction of masonry walls and for memorials. These products are quite distinct from crushed, broken, and pulverized stone, which comprises irregular fragments or grains sized chiefly by mechanical screening or air separation. Crushed and broken stone is covered in a later section of this chapter.

Dimension-stone producers may be divided into three main groups upon the basis of plant operation. The first group quarries stone and sells it as rough blocks or slabs; the second quarries stone and also manufactures it into finished products; and the third buys sawed slabs or rough blocks of stone and manufactures them into finished products but does not operate quarries. The Bureau of Mines statistical canvass covers the first and second groups but not the third group, which is more closely allied to the manufacturing than to the mining industries. Bureau of Mines statistics are compiled from reports of quantities and values of original sales; hence they include some material sold as rough blocks and some sold as finished products.

Total sales of dimension stone in 1943 declined 38 percent in quantity and 22 percent in value compared with 1942. These figures include slate, but details of this branch of the industry are given in the separate chapter on Slate.

The following table presents salient statistics for 1942 and 1943. The second table following is a historical record of the dimension stone industry from 1916.

Dimension stone sold or used by producers in the United States, 1942–43, by kinds and uses

Kind and use	1942	1943	
		Total	Percent of change
Granite:			
Building stone:			
Rough construction ... short tons	36,380	19,100	−47
Value	$132,276	$38.053	−71
Average per ton	$3 64	$1.99	−45
Cut stone, slabs, and mill blocks ... cubic feet	413,180	103,830	−75
Value	$1,030,223	$212,557	−79
Average per cubic foot	$2.49	$2.05	−18
Rubble ... short tons	215,730	65,850	−69
Value	$404,460	$120,296	−70
Monumental stone ... cubic feet	2,442,630	2,167,760	−11
Value	$7,092,572	$7,474,882	+5
Average per cubic foot	$2.90	$3.45	+19
Paving blocks ... number	1,986,910	637,370	−68
Value	$188,830	$66,542	−65
Curbing ... cubic feet	200,540	64,780	−68
Value	$232,392	$79,124	−66
Total:			
Quantity ... approximate short tons	522,170	283,880	−46
Value	$9,080,753	$7,991,454	−12
Basalt and related rocks (trap rock):			
Building stone:			
Rough construction ... short tons	4,880	101,330	+1,976
Value	$12,652	$105,669	+735
Average per ton	$2.59	$1.04	−60
Rubble ... short tons	7,870	24,000	+205
Value	$3,869	$13,104	+239
Total:			
Quantity ... short tons	12,750	125,330	+883
Value	$16,521	$118,773	+619

Dimension stone sold or used by producers in the United States, 1942–43, by kinds and uses—Continued

Kind and use	1942	1943	
		Total	Percent of change

[1] To avoid disclosing confidential information, sandstone paving blocks are included under "Curbing."

BUILDING STONE

The use of stone as a building material predates the most ancient historic records, but its employment under the war conditions that prevailed in 1943 declined to the lowest point in its recorded history. The following table gives the quantity and value of each kind of building stone used in 1943.

Building stone sold or used by producers in the United States in 1943, by kinds

Kind	Rough			
	Construction		Architectural	
	Cubic feet	Value	Cubic feet	Value
Granite	227, 680	$38, 053	46, 570	$43, 464
Basalt	1, 192, 150	105, 669	....	....

[1] For granite, sawed stone corresponds to dressed stone for construction work (walls, foundations, bridges) and cut stone to architectural stone for high-class buildings.

GRANITE

Sales of granite in the form of dimension stone declined 46 percent in quantity and 12 percent in value in 1943 compared with 1942. Rough construction and architectural stone sales declined to little more than half those recorded for 1942, while the output of dressed building stone fell to less than one-fifth of that recorded for 1942 in both quantity and value. The memorial stone branch of the industry, however, was maintained at relatively high levels. Rough stone sales dropped moderately in quantity, but the value was higher than in 1942. Dressed stone gained both in quantity and value. Curbing and paving-block production dropped to the lowest points ever recorded.

Granite (dimension stone) sold or used by producers in the United States in 1943, by States and uses

[1] Included under "Undistributed."

[2] 227,680 cubic feet (approximate).

The following tables show sales of monumental granite in the Quincy (Mass.) and Barre (Vt.) centers.

Monumental granite sold by quarrymen at Quincy, Mass., 1939–43 [1]

Year	Active plants	Cubic feet	Value
1939	3	25,620	$61,955
1940	3	24,540	60,139
1941	3	26,670	65,062
1942	3	16,738	$46,079
1943	1	12,603	45,274

[1] Quincy granite is sold also for construction, curbing, rubble, riprap, and crushed stone.

Monumental granite sold by quarrymen in the Barre district, Vermont, 1939–43 [1]

Year	Cubic feet	Value
1939	684,310	$2,029,801
1940	601,190	2,039,960
1941	764,280	2,431,152
1942	612,220	$2,035,327
1943	635,350	2,267,777

[1] Barre granite is sold also for construction and crushed stone.

Estimated output of monumental granite in the Barre district, Vermont, 1941–43 [1]

	1941	1942	1943
Total quarry output, rough stock……cubic feet	668,544	750,000	578,148
Shipped out of Barre district in rough……do	133,709	150,000	115,630
Manufactured in Barre district……do	534,835	600,000	462,518
Light stock consumed in district……do	334,272	468,750	289,074

Average number of days worked	230	230	222
Total pay roll for year	$3,729,600	$2,829,575	$2,539,236
Estimated overhead	1,864,800	1,414,787	1,269,618
Estimated value of light stock	1,398,605	1,640,625	1,318,900
Estimated value of dark stock	1,097,367	1,265,625	1,008,146
Estimated polishing cost	422,988	474,525	365,794
Output from saws	140,996	158,175	121,931
Total value of granite	8,654,356	7,783,312	6,623,625

[1] Through the kindness of the Granite Manufacturers' Association, Barre, figures covering the entire granite industry of the Barre district are given in this table to supplement figures of sales reported by quarrymen.

BASALT AND RELATED ROCKS (TRAP ROCK)

Because of its dark color, basalt is not employed extensively for building. Unusually large quantities, however, were used for rough construction in 1943, although the value per ton dropped from $2.59 to only $1.04. Sales of rubble also gained greatly, and the unit value was higher than in 1942. Basalt and related rocks are used to some extent for memorials, but such stones are classed in trade as black granite and are therefore included with the figures for monumental granite.

Basalt and related rocks (trap rock) (dimension stone) sold or used by producers in the United States in 1943, by States and uses

State	Active plants	Building stone				Total	
		Rough construction		Rubble		Short tons	Value
		Short tons	Value	Short tons	Value		
Connecticut	1	(1)	(1)			(1)	(1)

[1] Included under "Undistributed."

[2] 1,192,150 cubic feet (approximate).

MARBLE

Sales of marble in 1943 declined 11 percent in both quantity and value compared with 1942. The greatest decrease—51 percent in quantity and 48 percent in value—was in marble used for building purposes. War construction—which, as in 1942, dominated the building program—includes very few structures that employ marble. The erection of public, educational, and commercial buildings of permanent types, such as are built under peacetime conditions, has been virtually at a standstill since the war began; until such peacetime building is resumed, the building-marble industry will lag. On the other hand, the monumental branch of the industry, activity of which is governed largely by buying power of the public, made substantial gains in 1943, registering a 27-percent increase in quantity and a 20-percent increase in value of sales. The average value per cubic foot of building marble increased 6 percent, whereas that of monumental marble declined 5 percent.

LIMESTONE

Limestone fabricated as dimension stone is employed almost exclusively for building purposes. It is the most widely used building stone in the United States, and under normal conditions many million cubic feet are employed for both interiors and exteriors of public buildings of all kinds, including churches, museums, schools, and college buildings, as well as commercial and other privately owned structures. With virtual cessation during recent years of all types of construction that ordinarily use building stone the industry has experienced a serious decline, and there is no hope of recovery until peace prevails. The Indiana industry, centered at Bedford and Bloomington, supplied 79 percent of the rough architectural and finished (sawed and cut) limestone sold in 1943. Total sales in 1943 were 49 percent less in quantity and 63 percent less in value than in 1942. Unit prices of rough construction and of finished (cut and sawed) stone declined, but those of rough architectural stone and rubble increased.

SANDSTONE

Sales of sandstone declined 56 percent in quantity and 40 percent in value in 1943 compared with 1942. All branches of the industry experienced serious declines, the greatest of which—71 percent in both quantity and value—was in sales of rough construction stone. The average value of this product increased from $2.06 to $2.09 a ton. Cut stone, slabs, and mill blocks declined 16 percent in quantity and 20 percent in value, and the unit value dropped from $1.48 to $1.41 a cubic foot. Curbing and flagging sales were far below those of 1942. The paving-block branch of the industry is insignificant. The number of active sandstone plants dropped from 82 to 50.

Ohio is the leading producer, its quarries supplying 63 percent of the total value of output in 1943. The largest quarries are near Amherst, west of Cleveland. Pennsylvania, New York, Tennessee, and West Virginia follow in order of sales value.

The second table following presents a 21-year history of the bluestone industry. This type of sandstone, which splits readily into smooth sheets, is well adapted for building stone, curbing, and flagging. Sales in 1943 were little more than half those of 1942.

Sandstone (dimension stone) sold or used by producers in the United States in 1943, by States and uses

[1] New York and Pennsylvania are the only States that produce bluestone.

MISCELLANEOUS STONE

The following table gives data on certain types of dimension stone not included in the major groups already discussed. The principal varieties are mica schist, argillite, various light-color volcanic rocks, soapstone, and greenstone. The quantity sold in 1943 decreased 40 percent and the value 20 percent compared with 1942.

Miscellaneous varieties of stone (dimension stone) sold or used by producers in the United States in 1943, by States and uses

[2] Building stone (rough and dressed), approximately 370,060 cubic feet; flagging, approximately 13,470 cubic feet.

TRENDS IN USE OF DIMENSION STONE

Figure 1 shows graphically the history of production of dimension stone, by kinds, for a 28-year period. All types of stone follow closely the general trends of national peacetime prosperity, but they decline greatly during wars.

Figure 2 traces the history of production of all building stones and of the principal variety—limestone—in their relation to nonresidential building, the class of construction using stone most extensively. In peacetime, building stone follows the general trend of nonresidential construction, falling to low levels in depressions and reaching high points in periods of national prosperity when the building trades are vigorous. The striking divergence of the lines in figure 2 since 1941 illustrates the blighting effect of war on the building-stone industries.

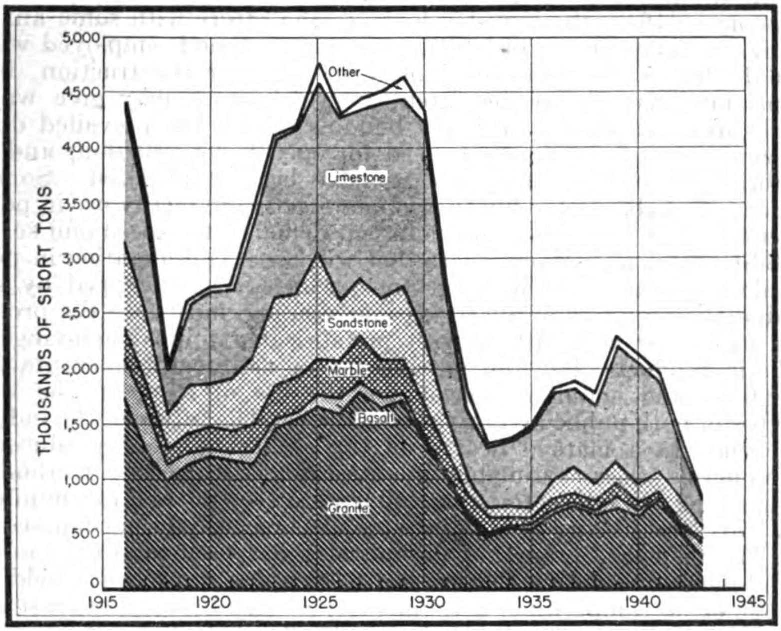

FIGURE 1.—Sales of dimension stone in the United States, by kinds, 1916–43.

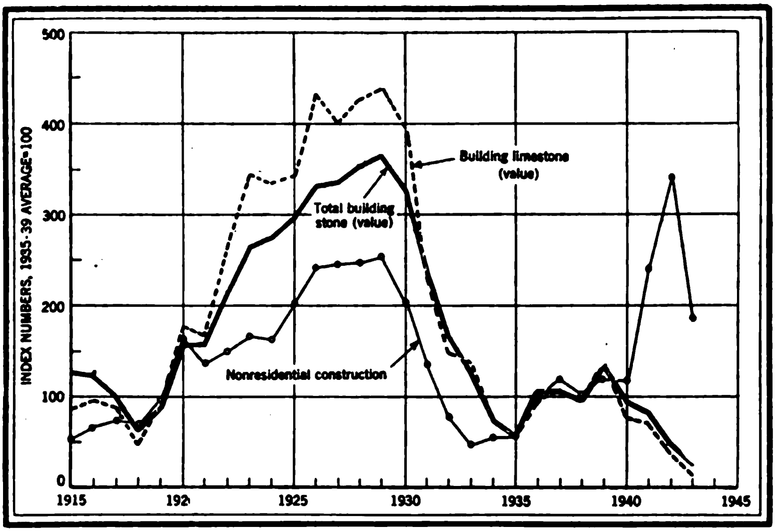

FIGURE 2.—Sales of all building stone and building limestone compared with nonresidential construction (public and private), 1915–43. Data on nonresidential building construction from Bureau of Foreign and Domestic Commerce.

POST-WAR OUTLOOK

As the use of building stone reached the lowest point in its recorded history in 1943, the industry looks to the future with some anxiety. The permanent types of buildings in which stone is employed will no doubt find their accustomed place in post-war construction, but a question arises as to the extent to which stone may give way to substitute materials. Military building, which has prevailed during recent years, has created a need for speedy construction, and prefabrication methods and designs have been emphasized. Some of them no doubt are too flimsy and unattractive to justify use in permanent structures, but out of the urgent demands for speed and serviceability there may evolve ideas that will merit consideration in peacetime construction. Building stone, which is handicapped by slow, laborious processes of quarrying and shaping, must face the prospect of increasing competition with prefabricated units employing synthetic products, but the advantages of architectural adaptability, dignity, and endurance encourage the use of stone in the better types of both public and private building. The future of the industry depends to a marked degree on the ability of stone producers to popularize these estimable qualities and to perfect methods of quarrying and fabrication that will tend to keep the cost to a minimum. A statistical history of building stone has recently been compiled.[1]

The memorial branch of the industry has been retarded less than building stone during the war; as it occupies an exclusive field with little or no competition, a volume of post-war business at least equal to that of pre-war years is to be expected.

CRUSHED AND BROKEN STONE

Over 170,000,000 short tons of crushed and broken stone were sold in 1943, exclusive of that used for making cement and lime. Sales decreased 12 percent in quantity and 9 percent in value compared with 1942. The average value at point of origin increased 3 cents a ton.

The following table of salient statistics shows the quantity and value of crushed and broken stone sold during 1942 and 1943, by uses. Detailed data on asphaltic stone and slate granules and flour are given in the chapters on Asphalt and Slate.

Slate granules and flour	483,740	3,404,416	7.04	395,550	2,923,888	7.3

[1] Value reported as cement in chapter on Cement.
[2] No value available for stone used in manufacture of cement and lime.
[3] Value reported as lime in chapter on Lime.
[4] Corrected figure.

The first and second tables following show the tonnage and value of stone used for concrete aggregate, road construction, and railroad ballast for a series of years and by States for 1943; the third is a historical table covering the output of crushed and broken stone, beginning with 1916.

Concrete and road metal and railroad ballast sold or used by producers in the United States, 1939–43

Year	Concrete and road metal		Railroad ballast		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1939	96,894,220	$88,988,217	6,996,800	$4,970,058	103,891,020	$93,958,275
1940	92,814,090	86,331,273	7,454,300	5,231,815	100,268,390	91,563,088
1941	110,192,610	106,985,808	10,771,300	7,536,451	120,963,910	114,522,259
1942	107,701,010	105,583,801	17,566,640	10,810,977	125,267,650	116,394,778
1943	82,412,380	83,397,757	17,235,700	11,346,272	99,648,080	94,744,029

COMMERCIAL AND NONCOMMERCIAL OPERATIONS

The following table shows the production of crushed stone for concrete and road metal during recent years by Government agencies of various kinds, contrasted with that by commercial enterprises. A striking change has occurred since 1939 in the ratio of commercial to noncommercial output. In that year 46 percent of total production was classed as noncommercial. It was applied largely to Government-sponsored make-work projects designed to combat unemployment. As war activities have solved the unemployment problem such projects are no longer necessary, and the noncommercial output dropped in 1943 to a mere 9 percent of the total.

Concrete and road metal sold or used by commercial and noncommercial operators in the United States, 1939–43

igures for "noncommercial operations" represent tonnages reported by States, counties, municipalities, and other Government agencies, produced either by themselves or by contractors expressly for their consumption, often with publicly owned equipment; they do not include purchases from commercial producers. Figures for "commercial operations" represent tonnages reported by all other producers]

Year	Commercial operations				Noncommercial operations				Total	
	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Percent of change in quantity from preceding year
939	52,519,470	$0.88	−3	54	44,374,750	$0.97	+29	46	96,894,220	+9
1940	55,748,940	.87	+6	60	37,065,150	1.02	−16	40	92,814,090	−4
1941	75,588,820	.94	+36	69	34,603,790	1.04	−7	31	110,192,610	+19
1942	92,251,930	.97	+22	86	15,449,080	1.05	−55	14	107,701,010	−2
1943	74,906,610	1.01	−19	91	7,505,770	1.05	−51	9	82,412,380	−23

GRANULES

The following table presents for the first time the production of roofing granules of all kinds.

Roofing granules sold or used in the United States, 1942–43, by kinds

Year	Natural		Artificially colored		Brick		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1942	352,320	$2,650,503	538,310	$7,594,174	43,230	$636,961	933,860	$10,881,638
1943	287,090	2,190,143	543,870	7,745,452	47,650	716,685	878,610	10,652,280

SIZE OF PLANTS

The chapter on Stone covering 1942 included for the first time statistics of crushed-stone production according to size of plant. That analysis applied to 1941, and presented herein is a similar table for 1942. The most evident trend from 1941 to 1942 was the increase both in number of the larger plants and in the proportion of total output represented by them. This was to be expected because a considerable proportion of the output during 1942 was applied to war uses, such as airfields, fortifications, and military roads, including many large projects that tended to centralize aggregate demands in certain areas. On the other hand, the reduction in general market requirements was disadvantageous to many small- and moderate-size plants.

Number and production of commercial crushed-stone[1] plants in 1942, by sizes of output

Range of output	Number of plants	Total production of plants (short tons)	Percent of total	Cumulative total (short tons)
Less than 1,000 tons	126	62,620	0.04	62,620
1,000 to 25,000	769	7,562,960	4.54	7,625,580
25,000 to 50,000	228	8,238,490	4.94	15,864,070
50,000 to 75,000	123	7,520,850	4.51	23,384,920
75,000 to 100,000	80	7,053,010	4.23	30,437,930
100,000 to 200,000	178	24,643,640	14.78	55,081,570
200,000 to 300,000	74	17,923,330	10.75	73,004,900
300,000 to 400,000	44	14,662,800	8.79	87,667,700
400,000 to 500,000	28	12,306,650	7.38	99,974,350
500,000 to 600,000	15	8,372,460	5.02	108,346,810
600,000 to 700,000	6	4,019,040	2.41	112,365,850
700,000 to 800,000	9	6,720,620	4.03	119,086,470
800,000 to 900,000	6	5,193,970	3.12	124,280,440
900,000 tons and over	23	42,447,690	25.46	166,728,130
Total	1,709	166,728,130	100.00	166,728,130

[1] Exclusive of marble, which is primarily a dimension-stone industry.

METHODS OF TRANSPORTATION

The following table shows the quantities of concrete and road metal conveyed during 1942 and 1943 by each of the principal methods of transportation. The trend evident for several years toward the use of trucks for a larger and larger percent of the total was reversed in 1942 and 1943.

Concrete and road metal sold or used by commercial producers in the United States, 1942–43, by methods of transportation [1]

Method of transportation	1942		1943	
	Short tons	Percent of total	Short tons	Percent of total
Truck	50,830,270	55	41,457,070	55
Rail	27,932,080	30	22,248,420	30
Waterway	4,311,930	5	3,241,420	4
Unspecified	9,177,650	10	7,959,700	11
	92,251,930	100	74,906,610	100

---

[1] For practical purposes the entire output of noncommercial operations commonly is moved by truck. Including noncommercial production, crushed stone for concrete and road metal moved as follows—1942: Truck 62 percent, rail 26 percent, water 4 percent, and unspecified 8 percent; 1943: Truck 59 percent, rail 27 percent, water 4 percent, and unspecified 10 percent.

GRANITE

Sales of crushed and broken granite declined 34 percent in quantity and 31 percent in value in 1943 compared with 1942. The greatest decline was in riprap. As very little harbor or shore-protection work was deemed essential to the war program in 1943, sales of riprap declined to only about one-eighth of their 1942 volume. Granite for concrete aggregate and road building declined 27 percent in quantity and 26 percent in value. The recession may be attributed to completion of many airfields, roads, and other structures essential to the military program. Railroad-ballast sales however gained 11 percent in quantity and 15 percent in value. The increase doubtless reflects the necessity of keeping the roadbeds of overworked railroads in adequate repair. The unit values at the quarry of concrete and road metal and railroad ballast increased 2 and 4 cents per ton, respectively.

The number of individual operations supplying noncommercial crushed stone cannot be determined with any degree of accuracy from the reports submitted. Therefore, in the accompanying tables covering granite and other kinds of crushed and broken stone, the number of active plants is not given. For many years before 1939, when noncommercial production was less important, such figures appeared in the tables.

Granite (crushed and broken stone) sold or used by producers in the United States in 1943, by States and uses

[1] Includes stone used for poultry grit and stone sand.

[2] Included under "Undistributed."

BASALT AND RELATED ROCKS (TRAP ROCK)

The dark igneous rocks—basalt, gabbro, and diorite—known commercially as trap rock, are used widely for highway construction and concrete aggregate. Sales of crushed and broken trap rock were 19 percent less and the value was 16 percent less in 1943 than in 1942. The value per ton increased from $1.19 to $1.23. Sales of riprap declined 9 percent in quantity and 19 percent in value, and the average return per ton decreased from $1.11 to 99 cents. Sales of trap rock for concrete aggregate and road construction declined 24 percent in quantity and 19 percent in value, although the value per ton increased from $1.18 to $1.25. For the same reason as mentioned in the preceding section on granite, sales of railroad ballast increased 17 percent in quantity and 27 percent in value. The value per ton increased from 91 cents to $1.

Basalt and related rocks (trap rock) (crushed and broken stone) sold or used by producers in the United States in 1943, by States and uses

[1] Includes stone sold for base course, fill material, roofing granules, and unspecified uses.

[2] Included under "Undistributed."

MARBLE

Large quantities of waste accumulate at marble quarries and finishing mills. Most of it is virtually pure calcium carbonate that is interchangeable with high-grade limestone for all the uses of the latter product. Producers of building and monumental marble are able therefore to find outlets for their waste stone in the form of crushed and pulverized products. As the following table indicates, the price per ton realized varies greatly, because some States produce relatively high priced products, such as terrazzo, stucco, and marble flour, that may sell for several dollars a ton, whereas other States find outlets only in the form of riprap, roadstone, and concrete aggregate that may command prices of only $1 or less per ton.

Marble (crushed and broken stone) sold by producers in the United States in 1943, by States [1]

State	Active plants	Short tons	Value	State	Active plants	Short tons	Value
Alabama	2	(2)	(2)	Utah	1	6,140	$66,459
California	1	1,060	$7,500	Virginia	1	240	2,003
Georgia	1	14,000	14,550	Washington	1	170	660
Maryland	1	(2)	(2)	Undistributed		56,780	236,535
Missouri	2	3,350	16,560				
New York	1	20,410	133,805		15	125,400	530,543
Tennessee	3	23,250	52,471	Average unit value			$4.23
Texas	1	(2)	(2)				

[1] Includes agriculture, artificial stone, crushed stone, mineral food, poultry grit, riprap, spalls, stucco, terrazzo, tile, and whiting (excluding marble whiting made by companies that purchase their marble).

[2] Included under "Undistributed."

LIMESTONE

Limestone sales were reported to the Bureau of Mines from 45 States in 1943. Because limestone is of wide occurrence, in many areas it is the most convenient kind of stone for highway or building construction and railroad ballast. The over-all cost of quarrying and crushing this stone is generally lower than that of the harder rocks. Limestone is an essential raw material for many metallurgical, chemical, and processing industries for which no other kinds of stone can be substituted. As a result of these various favorable conditions, it is by far the most widely used type of stone in the United States. In 1943 limestone constituted 76 percent of all crushed and broken stone sold (excluding that used for making cement and lime).

Sales in 1943 were 9 percent lower in quantity and 7 percent lower in value than in 1942. Riprap sales made moderate gains, but the value per ton declined from $1.09 to 97 cents. Fluxing-stone sales gained 4 percent to reach an all-time high. The low level of highway building and private construction in 1943 was reflected in a drop of 24 percent in quantity and 23 percent in value of limestone sold for concrete and road metal uses. Railroad-ballast sales declined moderately, but high farm income and the urgent call for increased farm crops stimulated a 6-percent gain in sales of agricultural limestone. Sales for uses other than the five major applications already mentioned are itemized in a following table.

Limestone (crushed and broken stone) sold or used by producers in the United States in 1943, by States and uses

State	Riprap		Fluxing stone		Crushed stone				Agriculture		Other		Tota

Use unspecified	91,230	245,279	66,630	186,876
	13,199,900	14,919,089	15,545,430	18,582,591

[1] Includes stone for filler for calcimine, chewing gum, explosives, leather goods, linoleum, paint, paper, phonograph records, plastics, pottery, putty, roofing, rubber, and unspecified uses.

[2] Figures not available.

[3] Includes refractory magnesia.

[4] Includes stone for acid neutralization, brick glazing, carbon dioxide, ceramics, chemicals (unspecified), concrete blocks and pipes, dye, electric products, motion-picture snow, oil-well drilling, rayon, rice milling, spalls, spray, sulfuric acid, and water treatment.

Dolomite (calcium-magnesium carbonate), which occurs extensively in the United States, is attaining increasing commercial importance. Dead-burned dolomite is used as a refractory lining for metallurgical furnaces, and statistical data for this product (which is closely allied to lime) are given in the Lime chapter of this volume. Dolomite is sold for refractory use, also in the raw state, particularly for patching. Dolomite is used in considerable quantities as a source of magnesia (MgO), which may be applied to refractory use or may be employed in various other ways. In 1943, for the first time, dolomite was used extensively as an ore of magnesium metal. As indicated in the accompanying table, 887,830 tons were so employed in the United States. As dolomite has attained so great importance because of its magnesium content, the Bureau of Mines has compiled a comprehensive report[3] describing and discussing the economic features of all the known methods of separating magnesia from it.

Sales of dolomite and its primary product of calcination—dolomitic lime—for certain special uses are covered in the following table.

Dolomite and dolomitic lime sold or used by producers in the United States for specified purposes, 1942–43

	1942	1943
Dolomite for—		
Basic magnesium carbonate:		
Short tons	117,650	[1] 203,240
Value	$151,756	[1] $242,974
Magnesium metal:		
Short tons	(2)	887,830
Value	(2)	$891,350
Refractory uses:		
Short tons	1,354,090	1,105,560
Value	$1,197,386	$1,120,258

See footnotes at end of table.

Dolomite and dolomitic lime sold or used by producers in the United States for specified purposes, 1942–43—Continued

	1942	1943
Dolomitic lime for—		
Refractory (dead-burned dolomite):		
Short tons	1, 229, 357	1, 276, 725
Value	$10, 817, 634	$11, 243, 017
Paper mills:		
Short tons	85, 000	72, 000
Value	$604, 000	$524, 000
Total (calculated as raw stone) short tons	4, 100, 000	4, 900, 000

[1] Includes refractory magnesia.
[2] Figures not available.

Fluxing limestone has attained such importance that the Bureau of Mines has separated the figures by principal uses, as indicated in the accompanying table.

Sales of fluxing limestone, 1939–43, by uses

Year	Blast furnaces		Open-hearth plants		Other smelters [1]		Other metallurgical [2]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

1942	23, 663, 630	18, 523, 158	5, 843, 820	4, 886, 157	494, 720	460, 270	257, 080	277, 728	30, 259, 250	24, 147, 313
1943	24, 755, 920	18, 785, 578	5, 932, 900	4, 899, 369	671, 990	581, 325	209, 840	239, 295	31, 570, 650	24, 505, 567

[1] Includes flux for copper, gold, lead, zinc, and unspecified smelters.
[2] Includes flux for foundries, and for cupola and electric furnaces.

Limestone is quarried not only for use raw but also for manufacture into cement and lime. The large and important industries manufacturing these products are covered in separate chapters of Minerals Yearbook. It is of interest, however, to show in one table, as follows, the total tonnage of limestone consumed for all purposes.

Limestone sold or used for all purposes in the United States, 1941–43, in short tons

Use	1941	1942	1943
Limestone (as given in this report) (approximate)	133, 164, 000	142, 488, 000	128, 980, 000
Portland cement (including "cement rock") [1] Natural cement ("cement rock") [1]	42, 735, 000	47, 657, 000	35, 867, 000
Lime [2]	12, 159, 000	12, 208, 000	13, 193, 000
	188, 058, 000	202, 353, 000	178, 040, 000

[1] Reported in terms of cement in chapter on Cement.
[2] Reported in terms of lime in chapter on Lime.

SANDSTONE

Sales of crushed and broken sandstone were 13 percent higher in quantity and 39 percent higher in value in 1942 than in 1943. Ganister production exceeded the previous all-time high of 1942 by a wide margin. The notable increase in sales of sandstone applied to miscellaneous uses is due in part to more complete coverage of stone granules, and the marked increase in average value per ton from 85 cents to $2.37 resulted from evaluation of granules upon a crushed and screened basis rather than upon the crude lump-rock basis used heretofore.

MISCELLANEOUS STONE

Crushed and broken stone, other than the five principal varieties already discussed, includes light-color volcanic rocks, schists, boulders from river beds, serpentine, and flint. The following table shows sales of stone of these types, by States and uses, in 1943; such sales declined 25 percent in quantity and 30 percent in value compared with 1942.

Miscellaneous varieties of stone (crushed and broken stone) sold or used by producers in the United States in 1943, by States and uses

[1] Includes stone used for ballast for ships, filler (unspecified), ornamental concrete, poultry grit, refractory, road base, rock wool, roofing granules, spalls, and waste.

[2] Included under "Undistributed."

[3] Chats; figures collected by Joplin (Mo.) office of the Bureau of Mines.

[4] A small quantity of stone included with chats.

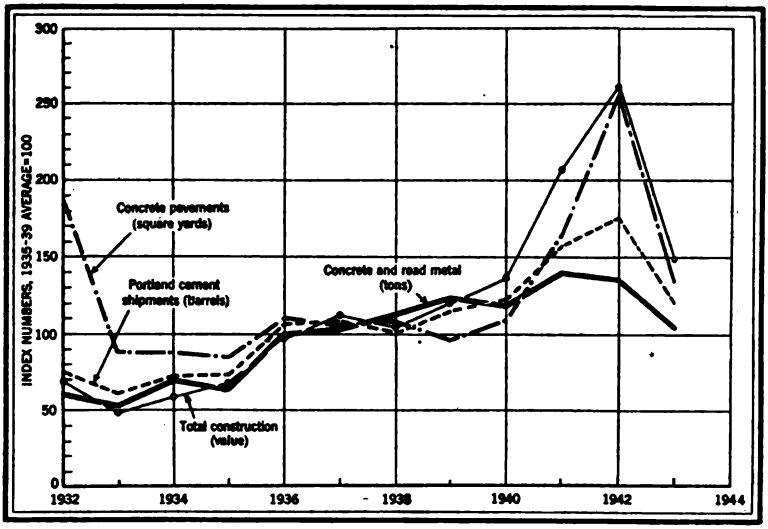

FIGURE 3.—Crushed-stone aggregates (concrete and road metal) sold or used in the United States compared with shipments of portland cement, total construction (value), and concrete pavements (contract awards, thousands of square yards), 1932–43. Data on construction and concrete pavements from Bureau of Foreign and Domestic Commerce.

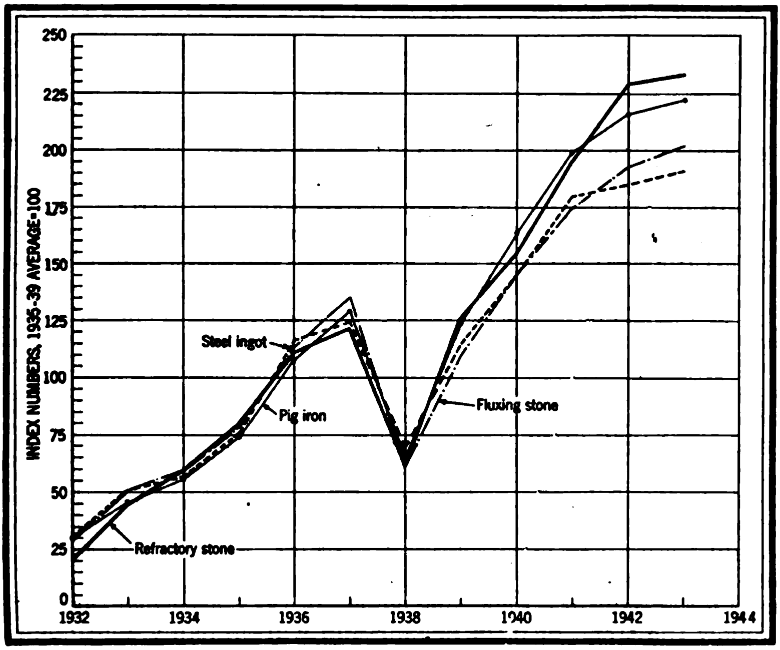

FIGURE 4.—Sales (tons) of fluxing stone and refractory stone, including that used in making lime, as recorded in the chapter on Lime compared with production of steel ingot and pig iron, 1932–43. Statistics of steel-ingot production compiled by American Iron and Steel Institute.

MARKETS

Crushed stone is used extensively as an aggregate in concrete for both highway and building construction. Sales should therefore normally follow the trends of cement shipments and area of concrete pavements that are constructed. These relationships are indicated in figure 3. Concrete pavements, the largest item of which was airfield runways, declined very greatly because most of such facilities were nearing completion by the end of the year. As total building-construction value declined more than 40 percent from the 1942 level, it is not surprising that both cement shipments and aggregates should decrease decisively.

The drastic downward trend in construction in 1943 found no counterpart in the metallurgical industries. Pig-iron production, which reached nearly 61 million tons, surpassed all previous records; therefore the demands for limestone furnace flux were the highest in the history of the stone industry. Steel-ingot production of nearly 89 million tons was also the highest on record. To replace burned-out furnace linings and to keep them in repair placed a heavy burden on producers of dolomite for refractory use and of ganister for making silica brick. The relations of fluxing-stone output to pig-iron production and of refractory stone to steel-ingot manufacture over a 12-year period are indicated in figure 4.

POST-WAR PROSPECTS

The principal uses for crushed stone are as aggregates in building construction and highways. The cumulative shortage of homes in the United States, according to some estimates, will demand new construction at a rate of a million residential units annually for 10 years after the war. A further accumulated need is in evidence for public and commercial buildings. Work on highway construction and repair, except for military roads, has been substantially reduced during the war period, and an insistent call for more and better highways is to be expected when travel restrictions are relaxed. Already plans, although somewhat nebulous, are taking shape for the construction of great superhighways that will bypass the maze of intersections that now impedes travel in intermediate cities. Prospective construction of many kinds furnishes reasonable assurance of a continuing moderate to strong demand for crushed-stone aggregates. National leaders are devoting much earnest thought to the avoidance of a great depression when peace comes, and no field offers greater promise of post-war employment than construction in its broadest sense. The aggregate industries will take a prominent part in any great building program.

A speedy transition from the current enormous output of munitions to construction and to the manufacture of civilian goods will afford reasonable assurance of substantial markets for flux and refractory stone and for that used in the chemical and processing industries. The demand for agricultural limestone which, in 1943, exceeded the supply, will follow the trend of farm income and will probably continue at a high level in the post-war era so long as food supplies must be augmented to feed a starving world. There is reasonable prospect therefore that all major branches of the crushed-stone industry may expect substantial market demands in the era after the war if plans for transition to a satisfactory peacetime economy materialize with reasonable success.

FOREIGN TRADE

As publication of foreign trade figures is still restricted for military reasons, no statistics of imports or exports can be given. They will, however, be published at the termination of the present war emergency to preserve the continuity of the statistical record.

Foreign trade in stone is relatively small. As indicated in the discussion presented in Minerals Yearbook, 1942, imports and exports of stone amount to only a fraction of 1 percent of average domestic sales. Therefore, their omission will not detract appreciably from the value of this report.

SLATE

SUMMARY

Slate production (which declined 5 percent in quantity and 15 percent in value in 1942 compared with 1941) decreased again in 1943. From the low level of 1942 it fell 21 percent in quantity and 23 percent in value. Except for granules used in composition roofing for various more or less temporary types of military construction, slate finds very limited application in the military program; and, as building construction fell to a very low level during 1943, use of dimension slate was confined primarily to repair and replacement work.

Roofing-slate sales fell 50 percent in quantity and 51 percent in value and reached the lowest point in the recorded history of the industry—less than one-tenth of the volume of sales 35 years ago. The average value per square in 1943 was $8.75, whereas in 1942 it was $8.87. In the Pennsylvania area sales were 39 percent lower in both quantity and value than in 1942. In the New York-Vermont area sales slumped to very low levels. Virginia sales dropped 43 percent in quantity and 38 percent in value.

Sales of mill stock decreased 18 percent in quantity and 16 percent in value. Sales of electrical slate, which had made decided gains during recent years, were 21 percent less in quantity and 17 percent in value; this doubtless reflects a recession in the establishment of new electrical facilities. As total new construction dropped from 261 percent of the 1935–39 average in 1942 to 149 percent in 1943, it is not surprising that sales of structural and sanitary slate dropped 39 percent in quantity and 36 percent in value. Military construction and war housing, which dominated the 1943 building program, use much smaller quantities of slate than normal peacetime building having the same dollar value. A decline of 42 and 43 percent in quantity and value, respectively, of blackboards and bulletin boards sold reflects the low level of new construction of educational institutions.

Sales of vaults and covers increased 50 percent in quantity and 55 percent in value. The remarkable gain of 100 percent in quantity and 111 percent in value of billiard-table tops reverses the trend of a year ago and indicates an increasing demand for recreational facilities, possibly because more spending money is available than heretofore.

Sales of school slates, most of which are exported, declined 18 percent in quantity and 9 percent in value. Sales of flagstones, stepping stones, and similar products decreased 19 percent in quantity but gained 19 percent in value.

Statistics on slate granules and flour are included in this chapter, although these products have little connection with the dimension-slate industry, except that granules are used in roofing products that compete in the roofing-slate market. For the most part, slate used for the manufacture of granules is unsuitable for other slate products. Sales of granules and flour declined 18 percent in quantity and 14 percent in value in 1943 compared with 1942. This was to be expected because the more or less temporary types of warehouse and barracks construction, as well as war housing that used large quantities of granule-surfaced roofing, had passed their peak in 1943. In that year the average sales value of granules f. o. b. mill was $8.71 and of flour $3.65 per short ton, compared with $8.29 and $3.53, respectively, in 1942. Figures for sales of granules made of rock other than slate are given in the chapter of this volume on Stone.

The following table presents the principal statistical data for the slate industry in 1942 and 1943.

Salient statistics of the slate industry in the United States, 1942–43

	1942			1943				
	Quantity		Value	Quantity		Value	Percent of change in—

[1] Square feet approximate. Number of pieces: 1942, 1,050,270; 1943, 863,270.
[2] Includes walkways, stepping stones, and miscellaneous slate.

SALES

Dimension slate.—Blocks or slabs cut to specified sizes and shapes are classed as dimension slate. This category includes all slate products except granules and flour. The following table shows sales of dimension slate for a 5-year period.

Slate (other than granules and flour) sold by producers in the United States, 1939–43

Year	Roofing			Mill stock		Other[1]		Total	
	Squares	Approximate equivalent short tons	Value	Approximate short tons	Value	Approximate short tons	Value	Approximate short tons	Value
1939	399,320	149,410	$2,868,961	21,710	$1,168,671	8,480	$63,493	179,600	$4,101,125
1940	347,180	127,600	2,436,123	17,070	935,810	9,780	64,435	154,450	3,436,368
1941	378,980	140,830	3,180,766	18,680	1,076,814	21,480	152,254	180,990	4,409,834
1942	192,070	71,400	1,704,053	18,720	1,112,426	16,910	139,328	107,030	2,955,807
1943	96,220	35,370	841,750	15,960	938,368	21,990	166,231	73,310	1,946,349

[1] Includes flagstones, walkways, stepping stones, and miscellaneous slate.

Figure 1 compares sales of roofing slate and mill stock with the number of new dwelling units and total new construction from 1920 to 1943. Roofing slate, which is used chiefly in residential construction, tends to follow the trend of activity in erection of new dwelling units, but since 1938 roofing-slate sales have failed to keep pace with it. In 1942 and 1943 new residential construction fell to an unusually low level, and the output of roofing slate declined correspondingly.

Mill-stock slate is used most widely in nonresidential building, but the types of construction that normally require slate have little place in the military program. Accordingly the great upsurge of new construction that characterized 1941 and 1942 afforded a minor stimulus to mill-stock sales, and the precipitous drop in total construction in 1943 was accompanied by a moderate recession in sales of slate from their low level of 1942. A return to the more permanent types of peacetime building would tend to stimulate a wider demand for structural slate.

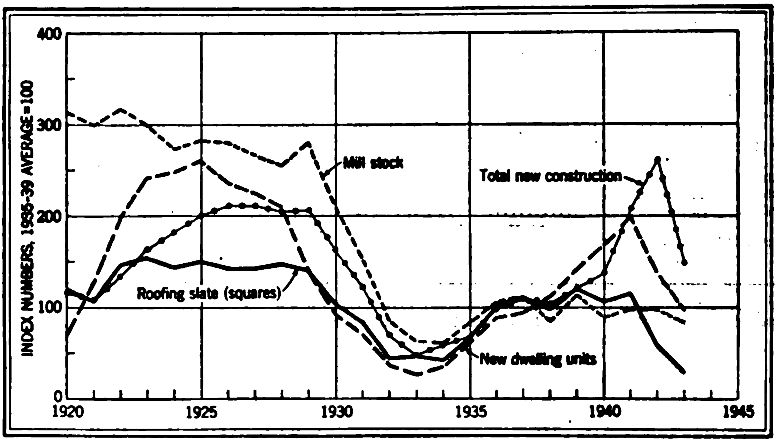

FIGURE 1.—Sales of roofing slate and mill stock compared with new dwelling units and total new construction, 1920–43. Data on new construction from Bureau of Foreign and Domestic Commerce and on new dwelling units from Bureau of Labor Statistics.

Figure 2 presents graphically a statistical history of slate over a 29-year period, by uses. Slate which, for the purpose of this figure, is designated "miscellaneous", including all mill stock except blackboards and bulletin boards as well as flagging, stepping stones, and other forms, maintained a value of sales nearly as high as in 1942, but roofing, blackboards, granules, and flour showed a marked decline.

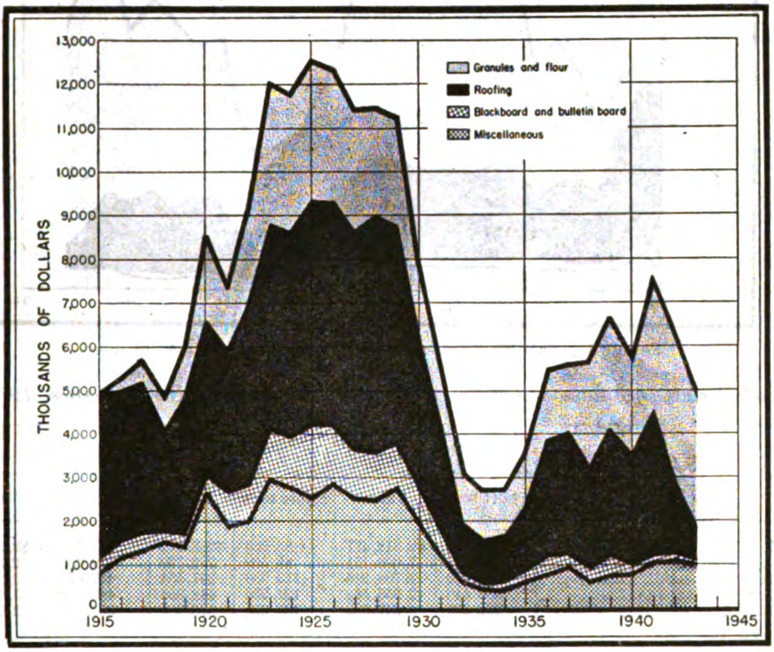

FIGURE 2.—Value of slate sold in the United States, 1915–43, by uses.

Figure 3 presents the history of slate production by kinds of products upon a quantity basis. Products of low unit value assume greater prominence in this chart than in figure 2, whereas the higher-priced products, such as blackboards, occupy a relatively insignificant place in figure 3.

Granules and flour.—Slate granules are used extensively in surfacing prepared roofing; and slate flour is employed as a filler in paints, road-asphalt surface mixtures, roofing mastic, oilcloth, and various other products. Although sales declined greatly in 1943 compared with 1942 they were, nevertheless, higher than in any pre-war year since 1929. The magnitude of sales was due chiefly to the wide use of granule-surfaced roofing on military establishments and war housing. Sales for a 5-year period are indicated in the accompanying table. The history of the industry and its more important technical and economic problems have been discussed in some detail by Josephson.[1]

PRICES

The average price of roofing slate, f. o. b. quarry or mill, as reported to the Bureau of Mines, decreased 12 cents a square in 1943 compared with 1942. In Pennsylvania it decreased 9 cents a square; in the New York-Vermont area it increased 43 cents, and in Virginia 90 cents.

The price of mill stock was unchanged at 35 cents a square foot. The average value of electrical slate increased 4 cents a square foot, structural and sanitary 2 cents, vaults and covers 1 cent, and billiard-table tops 1 cent; but the average value of blackboards remained unchanged. The sales value of granules and flour increased 35 cents a ton.

Price history.—Figure 4 shows the trend of slate prices compared with building materials in general over a 29-year period. Slate prices were lower than those of building materials from 1915 to 1920, but from that time until 1932 they were substantially above the average of all building materials. Since 1932 they have been in close accord, and in 1943 the index numbers were almost identical.

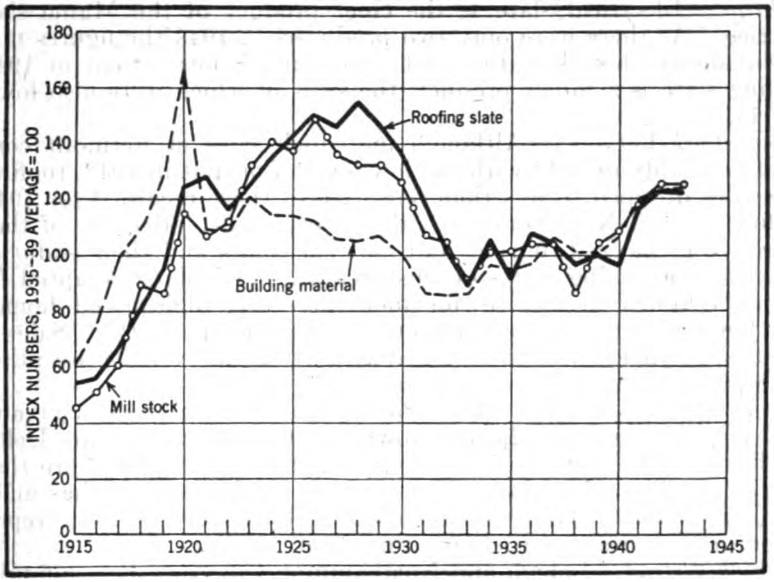

FIGURE 4.—Prices of slate compared with wholesale prices of building materials in general, 1915–43. Wholesale prices are from Bureau of Labor Statistics.

REVIEW BY STATES AND DISTRICTS

The following table gives sales of slate in 1943, by States and uses.

Slate sold by producers in the United States in 1943, by States and uses

State	Operators	Roofing		Mill stock		Other uses [1] (value)	Total value
		Squares (100 square feet)	Value	Square feet	Value		
Arkansas	1	-------	-------	-------	-------	[2]	[2]
California	1	-------	-------	-------	-------	[2]	[2]
Georgia	1	-------	-------	-------	-------	[2]	[2]
Maine	2	[2]	[2]	[2]	[2]	-------	[2]
Maryland	1	-------	-------	-------	-------	[2]	[2]
New York	5	120	$2,379	-------	-------	$611,187	$613,566
Pennsylvania [3]	21	77,270	648,237	2,129,740	$498,761	689,927	1,836,925
Vermont	12	[2]	[2]	[2]	[2]	1,145,378	1,284,288
Virginia	5	11,900	122,932	-------	-------	137,932	260,864

1942	68	192,070	1,704,063	3,213,410	1,112,426	3,543,744	6,360,223

[1] Flagging and similar products, granules, and flour.
[2] Included under "Undistributed."
[3] For details of production in Pennsylvania, see following table.

Maine.—Electrical slate is the chief product of the Maine slate quarries. As there were only two producers in 1943 the figures may not be shown; however, total sales were much lower than in 1942. Roofing slate is a minor product, the sales of which were also lower in 1943.

New York-Vermont.—Although mill-stock sales in Vermont compared favorably in 1943 with the low level of output in 1942, roofing-slate sales dropped to less than one-sixth of those recorded for 1942. Roofing sales in New York were almost negligible. Because of their attractive green, red, purple, and mottled colors and their enduring qualities, the roofing slates of this area are particularly adapted for public buildings as well as for moderate- and high-priced homes. Very few buildings in these categories were erected in 1943. Sales of granules, however, were maintained at fairly high levels because they find a place in wartime construction.

Peach Bottom district.—An area on the Maryland-Pennsylvania border, including the adjacent towns of Cardiff, Md., and Delta, Pa., has been the center of a slate-producing industry for more than 200 years. The sole roofing-slate producer in the territory has made slates since 1937. Granules and flour industries, which are represented in both States, experienced moderate declines.

Lehigh district.—Lehigh and Northampton Counties, Pa., comprise the most productive slate areas in the United States. Slate products of all the important kinds are made in this district. As separate figures may not be shown for York County, Pa., it is included with Northampton County in the accompanying table.

The value of total sales of slate products in the Lehigh district was 30 percent lower in 1943 than in 1942 and reached the lowest point in any year since 1935. Sales of roofing slate were down 39 percent in both quantity and value. The following mill-stock products gained in both quantity and value: Electrical slate (19 percent in quantity and 14 percent in value), vaults and covers (51 percent in quantity and 57 percent in value), and billiard-table tops (95 percent in quantity and 101 percent in value). The following products declined in both quantity and value: Structural and sanitary slate (38 percent in quantity and 34 percent in value), blackboards and bulletin boards (42 percent in quantity and 43 percent in value), and school slates (18 percent in quantity and 9 percent in value). Other products, chiefly granules and flour, decreased 29 percent in value compared with 1942.

Virginia.—Blue-black roofing slates are produced in Buckingham County. Sales were 43 percent less in quantity and 38 percent in value in 1943 than in 1942. Granules are produced at Esmont, Albermarle County, and New Canton, Buckingham County.

Other districts.—Slate granules and flour were produced near Mena, Polk County, Ark.; Placerville, Eldorado County, Calif.; and in Bartow County, Ga., near Fair Mount.

Slate sold by producers in Pennsylvania in 1943, by counties and uses

County	Operators	Roofing slate		Mill stock					
				Electrical		Structural and sanitary		Vaults and covers

[1] Small amount of slate for grave vaults and covers produced in Lehigh County included under Northampton and York Counties.

[2] York County produced roofing slate, granules, and flour only.

[3] Small amount of flagging produced in Lehigh County included under Northampton and York Counties.

NEW DEVELOPMENTS

The Pennsylvania Legislature has authorized a slate-research program to be conducted by Pennsylvania State College over a 2-year period. Slate is being studied from five angles—(1) test methods, (2) mineral composition, (3) physical and chemical properties, (4) component minerals of slate waste and methods of utilizing them, and (5) qualities and characteristics of new products made of slate. Work in under way on all of them, with special emphasis on microscopic, X-ray, and chemical studies of component minerals and manufacture of expanded slate aggregates.

POST-WAR PROSPECTS

The slate industry reached in 1943 the most inactive period in its history. Roofing slate, the principal product, finds its chief market in new residential construction, and as extensive home building is forecast for the immediate post-war era there is a fair prospect of a substantial revival in roofing-slate sales. Similarly, accumulated post-war public-building construction will call for increasing quantities of structural slate. Slate meets keen competition for every use to which it is applied, and the future prosperity of the industry will depend primarily on the success with which it meets such competition.

FOREIGN TRADE

Recent figures on foreign trade were omitted from the chapter on Slate in Minerals Yearbook, 1942, because of military restrictions. These restrictions still apply to data for 1942 and 1943, but 1941 figures have been released and are shown herein.. Data for 9 months only of 1941 had been published heretofore.

Imports.—Imports of slate into the United States are very small. Figures, by countries of origin, from 1937 up to and including the first 9 months of 1941, are given in the chapter on Slate in Minerals Yearbook, 1941. Total imports for the year 1941 were valued at $1,648.

Exports.—The following table lists the value of exports of slate products from 1937 to 1941, as reported to the Bureau of Mines by shippers.

Slate exported from the United States, 1937–41, by uses [1]

Use	1937	1938	1939	1940	1941

SUMMARY

In 1943 the United States had passed the peak of war construction, and emphasis had shifted to the production of armament. As over 90 percent of the output of the sand and gravel industry is used in construction, volume declined substantially. On the other hand, the industrial sands, which have essential functions in a wide variety of manufacturing processes, attained a new record.

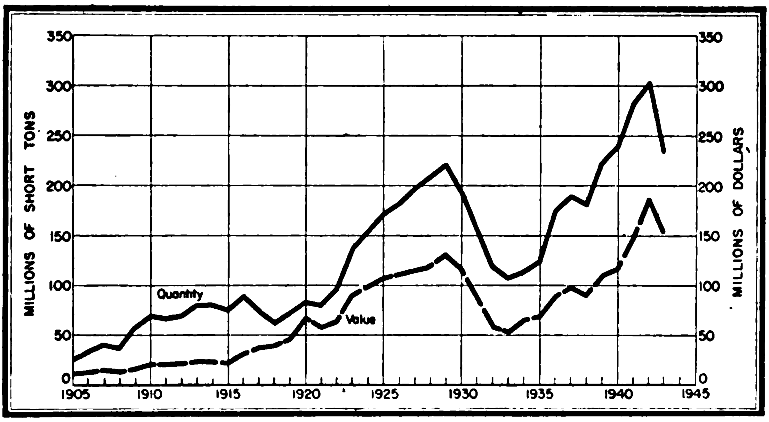

FIGURE 1.—Total production of sand and gravel in the United States, 1905–43.

Average values increased somewhat, but manpower, equipment, and other operating problems reduced production efficiency. Many plants experienced drastic reductions in volume as construction projects in their vicinity were completed. Even partly compensating demand from private or public construction programs was not expected to materialize until the war neared or reached its end.

POST-WAR OUTLOOK

It is generally agreed that a great backlog of demand for construction materials is being accumulated during the war. Road building and maintenance are being deferred. Many people want new dwellings. Whole new systems of dams are proposed. Even a considerable amount of industrial construction is anticipated, as many of the wartime structures have doubtful value under peacetime conditions.[1]

---

[1] Pit and Quarry, Post-War Outlook: Vol. 36, No. 7, January 1944, pp. 73–114.

Substantial private and public expenditures will be required to maintain a high level of sand and gravel production. The outlook for industrial activity after the war appears to assure a high rate of private spending in the immediate post-war years. The prospects for public expenditures, however, are still obscure because of uncertainty as to the magnitude of post-war public works programs.

As industrial sands are closely geared to manufacturing, their welfare will depend on the degree of general prosperity attained.

Sand and gravel sold or used by producers in the United States, 1942–43, by commercial and Government-and-contractor operations and by uses

[1] Includes blast sand as follows—1942: 422,922 tons valued at $1,071,018; 1943: 450,997 tons, $1,138,003.

[2] Includes ballast sand produced by railroads for their own use as follows—1942: 39,352 tons valued at $8,740; 1943: 28,032 tons, $5,399.

[3] Includes some sand used by railroads for fills and similar purposes as follows—1942: 178,191 tons valued at $27,500; 1943: 170,372 tons, $23,974.

[4] Includes ballast gravel produced by railroads for their own use as follows—1942: 10,243,680 tons valued at $2,031,339; 1943: 7,661,118 tons, $1,957,362.

[5] Includes some gravel used by railroads for fills and similar purposes as follows—1942: 1,294,861 tons valued at $141,917; 1943: 1,176,243 tons, $256,318.

[6] Approximate figures for States, counties, municipalities, and other Government agencies directly or under lease.

PRODUCTION

After increasing almost continuously during the previous 9 years, production of sand and gravel in 1943 declined 23 percent below the record set in 1942. The reduction was almost entirely in the construction types; the industrial sands attained a record tonnage 9 percent greater than in 1942. As producers' stocks of sand and gravel are comparatively small in tonnage and do not vary greatly from year to year, production virtually equals sales, and the two terms are used interchangeably throughout this report. The following table summarizes the production of sand and gravel in the United States during the past 5 years.

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States, 1939–43

Year	Sand		Gravel (including railroad ballast)		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1939	72,542,000	$41,608,000	153,466,000	$64,458,000	226,008,000	$106,066,000
1940	78,674,000	45,332,000	159,634,000	65,356,000	238,308,000	110,688,000
1941	103,835,000	62,152,000	184,880,000	85,055,000	288,715,000	147,207,000
1942	107,371,000	74,443,000	196,975,000	114,057,000	304,346,000	188,500,000
1943	82,053,000	62,263,000	152,011,000	90,530,000	234,064,000	152,793,000

California was again the leading producer, followed by Illinois, Texas, Ohio, and Michigan in that order. Six States exceeded 10 million tons in 1943, whereas nine reported that quantity in 1942. Details of production in 1943, by States and uses, are presented in the following tables.

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States in 1943, by States

[1] Included under "Undistributed."
[2] Includes items entered as "1."
[3] Includes 450,997 tons of blast sand valued at $1,138,003.
[4] Includes 28,032 tons of ballast sand valued at $5,399, produced by railroads for their own use.
[5] Includes 170,372 tons of sand valued at $23,974, used by railroads for fills and similar purposes.
[6] Includes 7,661,118 tons of ballast gravel valued at $1,957,362, produced by railroads for their own use.
[7] Includes 1,176,243 tons of gravel valued at $256,318, used by railroads for fills and similar purposes.

Government-and-contractor production.—Trends in Government-and-contractor production of sand and gravel noted in 1942 continued in 1943. Total output was 19 percent lower than in 1942. The contraction in this phase of the industry is indicated by the fact that in 1943 it produced 46 percent less than in 1939 whereas the same comparison for commercial operations shows 49 percent greater tonnage.

The decline was uniform among the various Government units; States reported 32 percent of the total, counties 25, municipalities 2, and other agencies (principally Federal organizations) 41—nearly the same percentages as in 1942.

Direct production by Government agencies continued to decline. In 1940 contractors supplied only 27 percent of the total tonnage, but by 1943 their contribution had increased to 56 percent.

Although it increased little in 1943 the average value, reflecting higher costs, is more than one-third higher than before the war. Other details are shown in the following tables.

Sand and gravel sold or used by Government-and-contractor producers in the United States, 1939–43, by uses

Year	Sand				Gravel				Total Government-and-contractor sand and gravel

METHOD OF TRANSPORTATION

Tire, gasoline, manpower, and maintenance problems are making the operation of trucks increasingly difficult. These difficulties are reflected in a trend toward rail transportation. Despite the fact that there was much less sand and gravel to move, commercial producers shipped a larger percentage of their output by rail than by truck in 1943; from 1938 to 1942 trucking had predominated. However, when the Government-and-contractor tonnage is considered trucks still lead by a wide margin. Waterways handle only a small fraction of the national total, but locally their facilities are important.

Sand and gravel sold or used by commercial producers in the United States, 1942–43, by methods of transportation [1]

Method of transportation	1942		1943	
	Short tons	Percent of total reported	Short tons	Percent of total reported
Truck	103,777,190	47.4	67,475,351	42.4
Rail	93,456,656	42.7	77,700,918	48.8
Waterway	21,603,759	9.9	13,974,693	8.8
Total reported	218,837,605	100.0	159,150,957	100.0
Percent of total commercial production covered		94.0		90.0

[1] For practical purposes the entire output of Government-and-contractor operations commonly is moved by truck. Including Government-and-contractor production, sand and gravel moved as follows—1942: Truck 60 percent, rail 32 percent, and waterway 8 percent; 1943: Truck 58 percent, rail 36 percent, and waterway 6 percent.

DEGREE OF PREPARATION

During the past 5 years 86 to 88 percent of the commercial tonnage has required preparation to meet specifications, whereas only 21 to 34 percent of the Government-and-contractor material has been prepared. Much of the sand and gravel produced during the past 2 years has gone into construction of war facilities that required close adherence to quality standards. This fact and the curtailment of public projects that use large quantities of unprepared material have combined to increase the over-all degree of preparation to 71 percent in 1943 (72 percent in 1942), substantially higher than the 63 percent averaged during 1935–39. As shown in the accompanying table, 92 percent of the processed tonnage was handled in commercial plants in 1943. As processing adds materially to the cost of the product, the average value of commercial output is always higher than that from Government-and-contractor operations.

Sand and gravel (prepared or unprepared) sold or used by producers in the United States, 1942–43, by commercial and Government-and-contractor operations

	1942			1943

SIZE OF PLANTS

Average plant size, which has increased greatly since 1940, began to readjust back toward the pre-war distribution. Average plant production declined from 87,000 tons in 1942 to 73,000 in 1943. The ranks of the very large plants, producing over 500,000 tons yearly, were depleted from 76 in 1942 to 39 in 1943, and their percentage of the total tonnage dropped from 29.2 percent to 20.6. Half of the total output was contributed by the 29.7 percent that reported between 50,000 and 300,000 tons in 1943. Nearly half the plants produced less than 25,000 tons. Details of output, by size groups, for 1942 and 1943, are given in the following table.

Comparison of number and output of commercial sand and gravel plants in the United States, 1942–43, by size groups [1]

Size group, in short tons	1942				1943			
	Plants [2]		Production		Plants [2]		Production	
	Number	Percent of total	Short tons	Percent of total	Number	Percent of total	Short tons	Percent of total
Less than 25,000	1,258	49.2	10,225,000	4.6	1,119	48.6	9,429,000	5.6
25,000 and less than 50,000	366	14.3	13,139,000	5.9	393	17.1	13,924,000	8.3
50,000 and less than 100,000	336	13.1	24,591,000	11.1	323	14.0	22,717,000	13.6
100,000 and less than 200,000	299	11.7	42,193,000	19.1	258	11.2	35,934,000	21.5

1,000,000 and over	18	.7	26,523,000	12.0	9	.4	14,191,000	8.5
	2,557	100.0	221,192,000	100.0	2,301	100.0	167,433,000	100.0

[1] Plants operated by or for States, counties, municipalities and other Government agencies are not included; also not included are approximately 172 railroad plants with an output of 11,756,000 tons of sand and gravel in 1942 and 165 plants with an output of 9,036,000 tons in 1943.

[2] Includes a few companies operating more than 1 plant but not submitting separate returns for individual plants.

PRINCIPAL TRENDS

Sand and gravel for construction.—Contract awards in the construction industry declined sharply in 1943. Building of war plants and other military facilities was nearing completion, and private building was discouraged by wartime limitations on the production and sale of hardware, wood, and other essential components. As erection programs based upon previous contracts were still active, consumption of sand and gravel did not decrease as much as contracts; consequently, further reductions are likely in 1944. Figure 2 shows the correlation between sales of sand and gravel and construction activity during the past 11 years.

Industrial sands.—In contrast with the construction types, industrial sand consumption continued to increase in 1943. As nearly all of these sands enter directly into manufacturing or closely allied operations they will be in great demand as long as production of war goods remains at a high level. Figures 3 and 4 show graphically the details of production of these sands in past years and their correlation with trends in industrial production.

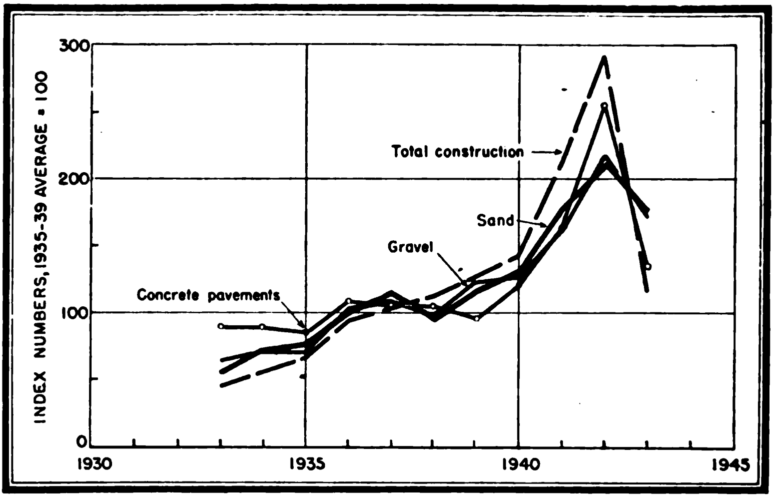

FIGURE 2.—Value of sand and gravel production compared with total construction (value) and concrete pavements (contract awards, thousands of square yards) in the United States, 1933–43. Data on construction and concrete pavements from Bureau of Foreign and Domestic Commerce.

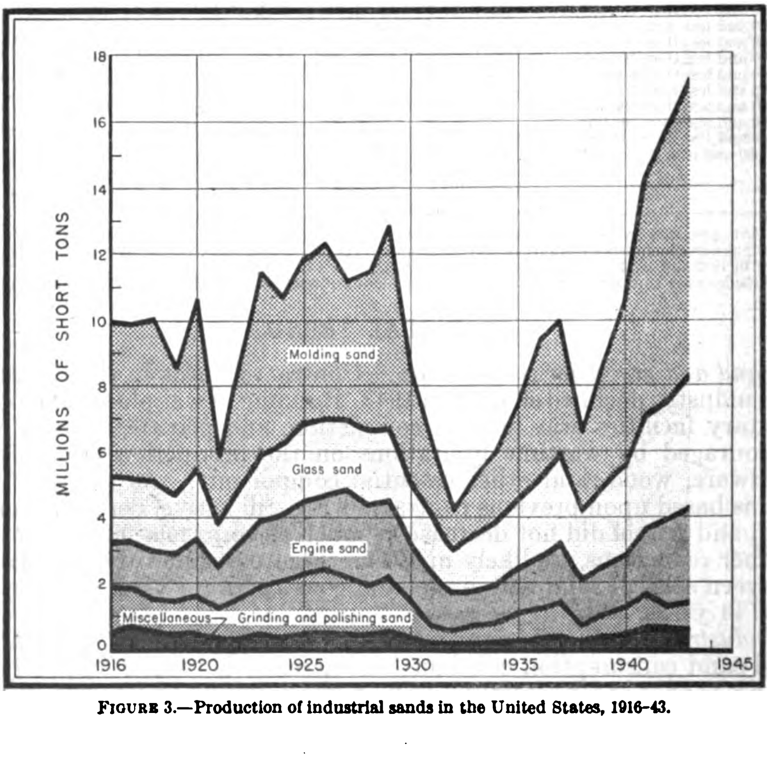

FIGURE 3.—Production of industrial sands in the United States, 1916–43.

EMPLOYMENT AND PRODUCTIVITY

Employment in the commercial sand and gravel industry reached a peak of nearly 32,000 men in 1942 and then declined to about 26,000 in 1943. Output per man-hour continued nearly as high in 1942 as in 1941 but declined to the pre-war level in 1943. As shown in the regional tables, this loss in efficiency, generally attributed to labor turn-over and reduced production, was Nation-wide. The number of working days per year increased in 1943, and owing to the manpower shortage the average length of shift remained at nearly 9 hours. The reports of operators who produce about four-fifths of the total tonnage are summarized in the accompanying tables.

Employment in the commercial sand and gravel industry, sand and gravel produced at plants included in the study, and average output per man in the United States, 1937–43 [1]

[1] Excludes plants operated by or directly for States, counties, municipalities, and other Government agencies.

PRICES

Most classes of sand and gravel showed modest increases in ton value in 1943. Commercial operators reported that sand averaged 9.9 and gravel 3.0 percent higher than in 1942; comparable figures for Government-and-contractor output were 8.3 and 5.0 percent, respectively. Details covering unit and total values for each class of sand and gravel are contained in the summary table at the beginning of this chapter.

Prices of sand and gravel were under the provisions of Maximum Price Regulation 188. In general, the ceiling prices established by the General Maximum Price Regulation were continued, but in a few instances upward revisions were approved by the Office of Price Administration. Adjustments were on an individual company or a marketing-area basis, rather than for the entire industry.

NEW DEVELOPMENTS

During the past few years, consumers have steadily raised the quality standards required of sand and gravel products. Demand for increased fines in aggregates is stimulating interest in methods of meeting the specifications and is leading to the introduction of additional processing equipment.[2]

Although treatment of sand to prevent stripping when used in asphalt road surfacing has not gained much headway, interest is being shown in various quarters, and experimental work is progressing.[3]

[3] Janssen, A. S., Furfural as an Anti-Stripping Agent: British Chem. and Physiol. Abs., October 1943, p. 410.

Derivatives of natural resins are expanding their sales in the foundry sand market. This binder is claimed to allow reuse of a high percentage of reclaimed sand.[4]

A new product that can be of importance to the glass-sand industry was introduced in 1943. A structural material of moldable plastic reinforced with glass fibers is said to have physical properties that compare favorably with metals and also to possess unique advantages in rapid low-cost fabrication.[5]

FOREIGN TRADE

Sand and gravel of all qualities are so abundant in the United States that the imported tonnage is a very small factor in the industry. During the period 1935–39 imports averaged only a little over 400,000 tons per year—about 0.23 percent of domestic production. During the same period exports averaged less than 50,000 tons annually. Tables showing foreign trade statistics for the years 1932–40 and 1941 (9 months only) were published in the Sand and Gravel chapter of Minerals Yearbook 1942. Owing to wartime restrictions no figures on current foreign trade can be published, but they will be released at the end of the war to preserve the continuity of the statistical record.

BLAST-FURNACE SLAG

The total output of air-cooled screened and unscreened, water-granulated, and lightweight slag for 1943 was 16,507,607 short tons compared with 19,122,718 tons for 1942. Sales of air-cooled slag were 4 percent less in 1943 than in 1942, and the average value per ton of screened declined 2 cents and unscreened 3 cents. These figures are based upon a canvass, conducted by the National Slag Association, of the 32 companies that prepare blast-furnace slag for commercial use, and the results were assembled in cooperation with the Bureau of Mines.

Air-cooled slag was used principally in the construction and maintenance of highways, access roads, airport runways, defense-plant and housing projects, miscellaneous structures, and as railroad ballast and sewage trickle filter media. Other uses and quantities involved are shown in the accompanying table.

Virtually all the commercial output is produced east of the Mississippi River, chiefly at steel centers in Ohio, Alabama, Pennsylvania, and Illinois. Shipments, however, are made into all States east of the Mississippi, except some of the New England States outside the economic range of source of supply. Shipments of slag are made by railroad, truck, and waterway. The accompanying tabulation shows the pattern of distribution during the past 4 years.

Shipments of commercial slag in the United States, 1940–43, by methods of transportation[1]

[Percent of total]

Method of transportation	1940	1941	1942	1943
Rail	55	55	52	56
Truck	44	43	47	44
Waterway	1	2	1	(2)

[1] National Slag Association.
[2] Less than 0.5 percent.

The average shipping range of blast-furnace slag in 1943 was 57 miles by rail, 14 by truck, and 157 by waterway. Generally shipments did not exceed 100 miles by railroad, 30 by truck, and 280 by waterway.

During the process of crushing and screening blast-furnace slag, particles of metallic iron that escape through the slag notch of the blast furnace are recovered at the slag plant by means of hand-picking and magnetic pulleys. During 1943 the companies surveyed reported 154,207 tons of metallic iron recovered and returned to the furnaces to bolster the supply of metal so vitally needed in the prosecution of the war. The yield slightly exceeds 1.1 percent or approximately 23 pounds of metallic iron per short ton of slag processed.

Not including those assigned to administrative, office, and sales activities, 1,550 plant and yard employees were engaged in producing commercial slag in 1943. The total number of man-hours in production was 4,194,496.

Air-cooled blast-furnace slag sold or used by producers in the United States, 1942–43, by States[1]

State	1942			1943

SUMMARY

The wartime controls on construction continued to have a depressing effect on the gypsum industry through 1943, and general activity fell sharply. The reduction in rate of operations from 1942 may be gaged by the 19-percent decrease in new crude supply to a total of 4,108,864 short tons and the 16-percent drop in production of calcined gypsum to 2,557,730 tons in 1943. However, the rate of decline in over-all activity was eased markedly through 1943, and in the fourth quarter the trend was nearly horizontal. Demand increased for certain prefabricated materials, and sales of wallboard and laminated board advanced to record volumes in 1943. In contrast, demand for the "built-in" products—plasters, lath, and tile—fell well below the 1942 level. Sales of all classes of industrial plasters advanced over the tonnage sold in 1942. Of the uncalcined products, the slump in indicated consumption of portland-cement retarder was offset partly by the increased sales of agricultural gypsum, which rose to a new high annual total in 1943. As a result of the strong demand for the relatively higher-valued prefabricated materials, the mill value of total sales by the industry decreased only 6 percent from 1942 to $59,096,532 in 1943. Regulation of prices of gypsum products by the Federal Government was continued through 1943 under maximum Price Regulation 188, and no changes were made in the permitted maximums, which had been frozen at the March 1942 levels.

The decline in general activity of the gypsum industry in 1943 was much less severe than the sharp drop in total construction. New construction activity in 1943 was estimated by the United States Department of Commerce to be 43 percent below 1942, and data of the Dodge Corporation on residential building contracts fell 52 percent in 1943. The favorable comparison for the gypsum industry may be attributed to the strong demand for some prefabricated products, industrial plasters, and agricultural gypsum, which cushioned the abrupt declines in sales of plasters, lath, tile, and cement retarder.

A basic cause of the selectivity in demand for gypsum products in 1943 as in 1942 was the war control on building. This regulation, Conservation Order L-41 of War Production Board, effective since April 9, 1942, was amended several times in 1943, and the revised form of November 1 appeared to be more restrictive in total effect on new construction than prior ones. The stoppage of nonessential public and private building under the order had resulted in a sharp decline in demand for lath, tiles, and building plasters. However, markets for wallboard, sheathing, and laminated board were enlarged by the gradual tightening in supplies of 1-inch construction lumber. The joint War Housing Construction Standards of the National Housing Agency and War Production Board, which were continued through 1943, prohibited the use of lumber for housing when suitable substitutes were available.

Salient statistics of the gypsum industry in the United States, 1939–43

	1939	1940	1941	1942	1943
Active establishments [1]	92	91	93	92	85
Crude gypsum [2]—					
Mined ... short tons	3,226,737	3,699,015	4,788,534	4,697,568	3,877,541

Building uses:					
Value	$42,627,260	$49,709,049	$64,734,171	$57,796,210	$53,722,762
Total value	$45,928,239	$53,492,644	$69,758,442	$63,170,744	$59,096,532
Gypsum and gypsum products—					
Imported for consumption	$1,363,967	$1,429,289	$1,282,140	$508,321	$304,070
Exported	$309,453	$264,128	$529,574	$977,863	$283,720

[1] Each mine, plant, or combination mine and plant is counted as 1 establishment.
[2] Excludes byproduct gypsum.
[3] Revised figure.
[4] Made from domestic, imported, and byproduct crude gypsum.

To alleviate a shortage of gypsum boards in the Pacific coast region, the Office of Price Administration issued the following amendments to Order A-1 under Maximum Price Regulation 188: Amendment 13, effective September 18, 1943; Amendment 19, effective December 1, 1943; Amendment 24, effective January 7, 1944; and Amendment 31, effective March 24, 1944. Under these special pricing provisions, gypsum boards for installation in projects under control of specified Federal Government agencies could be shipped into Arizona, California, Oregon, and Washington from plants as far east as Ohio at set mill prices plus full freight costs. The amendments differed only in the types of board and number of Government agencies included in the provisions. Amendment 31 applied to all types of board and is to expire July 1, 1944. Use of the special pricing amendments set up a means of relieving the board shortage without any adjustment of the March 1942 ceiling prices on these products in the consuming area. The Office of Price Administration ruled that, except in cases of proved hardship, gypsum producers who sell upon a delivered basis should not pass on but should absorb the 3-percent transportation tax of December 31, 1942. The ruling, which affects only the Pacific coast region and certain metropolitan areas in other sections of the country, was upheld by the Emergency Court of Appeals and the Supreme Court.

The feature of the industry was the marked demand for wallboard and laminated board, which was fostered in part by the shortage of 1-inch lumber and continued throughout 1943 despite the rapid decline in structural activity. Early in 1943 demand for wallboard appeared to be relatively strong in nearly all parts of the country, but by the fourth quarter only the record demand in the Pacific and Southern States maintained the high volume of sales. The rate of increase in sales had flattened to nearly a horizontal trend in the fourth quarter, and the long-term trend apparently was approaching a peak. Consumption of laminated products, which had been introduced about the middle of 1942, was nearly four times larger in 1943 than in 1942. In wartime construction, the laminated boards compete rather severely with sheathing, and as demand for the laminated products was maintained through 1943 that for sheathing declined.

Sales of the "built-in" gypsum materials—lath, building plasters, and tiles—declined in 1943 in contrast with the rising demand for the completely finished prefabricated products. Indicated consumption of lath fell sharply below that in 1942. However, the downtrend in sales of this product was interrupted during the October-December period for the first time since the trend started downward in the second quarter of 1942. The square footage of lath sold in the fourth quarter of 1943 was nearly one-fifth larger than in the corresponding period of 1942 and also advanced contraseasonally over the quantity sold in the third quarter of 1943. Demand for building plasters as a group slumped in 1943 with sales of base-coat and gauging and molding plasters, the important tonnage items, falling, respectively, 38 and 30 percent below those in 1942. Sales of these types declined at a rapid rate early in 1943, but by the October-December period the rate of decrease had eased markedly. The nearly similar behavior in trends of these companion products and of lath through 1943 would indicate that sales of the "built-in" materials may have fallen to the minimum required for necessary building and repair work.

The source composition of the new crude supply showed further changes in 1943. Owing to war restrictions on shipping, imports of crude fell to the lowest annual total since 1919 and represented only 6 percent of the new supply compared with 8 percent in 1942 and 22 percent in 1941. Although crude supplies were short at Atlantic tidal plants, the critical situation was mitigated somewhat by the fact that the greater demand for gypsum products in 1943 was in sections of the country not served from these plants. To provide relief for the supply problem at the processing plants on the Atlantic coast, substantial shipments of calcined gypsum were made from western New York into the New York City and Philadelphia areas and from western Virginia to the Georgia and Florida plants. In addition, the calcined output of a byproduct-gypsum plant was utilized at other nearby processing plants in the New York City area. Stocks of crude gypsum in the country on December 31 totaled 480,737 short tons, of which 126,304 tons were at Atlantic tidewater plants. Similar data for December 31, 1942, were total stocks of 741,549 tons, with 152,581 tons at the tidal plants.

The progressive easement in the rate of decline of new crude supply and calcined production through 1943 is depicted clearly by the flattening of the long-term trend curves of these materials in figure 1. The convergence of the new-crude-supply and domestic-crude-mined curves through 1942 and 1943 illustrates the drastic curtailment in crude imports, a condition that resulted in the lesser rate of decline in domestic mine output.

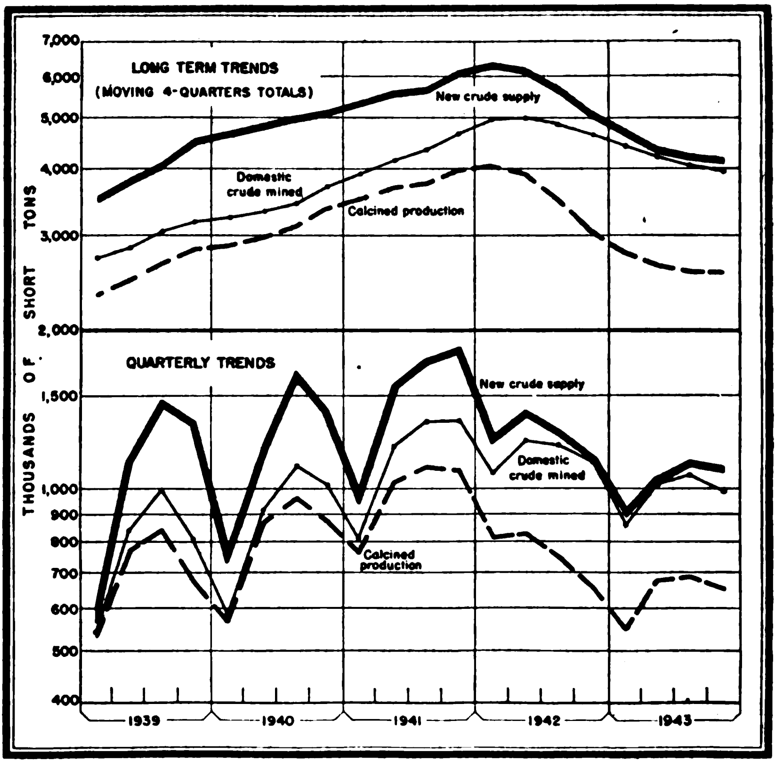

FIGURE 1.—Trends of new crude supply, domestic crude mined, and production of calcined gypsum, 1939–43, by quarters.

Court trial of the civil action[1] by the United States Department of Justice against seven gypsum companies and officials on charges of violating sections 1, 2, and 3 of the Sherman Antitrust Act opened November 19. The civil action raises the broad question of legality under the Sherman Act of the defendants' alleged price-fixing practices under patent-licensing agreements.

Labor for gypsum operations was critical in 1943, and the War Manpower Commission certified the mining and processing of gypsum and the production of gypsum boards to the list of activities essential to the war. Average monthly employment in the gypsum products industry during 1943, according to the United States Department of Labor, was 92.0 percent of the corresponding figure for 1939. Considerable overtime was worked in 1943, as is indicated by an average monthly wage-earner pay-roll index of 151.5 compared with 100.0 in 1939.

POST-WAR OUTLOOK

Although the outlook for the gypsum industry is not encouraging for the war's duration, post-war prospects are eminently favorable. Forecasts of residential building have unanimity in predicting large annual volumes for a period of years beginning immediately after removal of war restrictions on construction. Also, polls of public opinion reveal that the post-war demand will be predominantly for houses of the conventional type from which may be inferred continued use of the common pre-war structural materials. Gypsum products have prime advantages in the building field in that they are fire- and vermin-proof, will not warp, and are relatively low cost. In addition to the old-established line, two gypsum products—sheathing and laminated board—were accepted widely in war construction and apparently have bright futures in the post-war markets. New uses for industrial plasters, such as molds for metal casting and rubber products, forecast expanded consumption after the war. Demand for cement retarder and agricultural gypsum promises to be strong in the post-war period. All factors point toward brisk business for the gypsum industry after the war.

DOMESTIC PRODUCTION

Although output from domestic mines in 1943 virtually supplanted crude imports and represented 94 percent of the total new supply, domestic production fell 16 percent below 1942. Active operations totaled 56, comprising 26 underground mines, 24 open quarries, and 6 mine-quarry combinations. The average mill value of run-of-mine gypsum advanced to $1.54 per ton in 1943.

[1] Included under "Other States."

[2] By groups of States as follows—1941: Arkansas (1 active mine) and Kansas (2)—174,918 tons valued at $177,499; Colorado (2), Montana (2), South Dakota (1), and Wyoming (1)—149,848 tons, $222,710; Ohio (2) and Virginia (2)—513,421 tons, $804,511. 1942: Arizona (1), Arkansas (1), and Kansas (2)—142,731 tons, $170,403; Colorado (2), Montana (2), South Dakota (1), and Wyoming (1)—135,588 tons, $202.612; Ohio (2) and Virginia (2)—537,177 tons, $776,842. 1943: Arkansas (1), Kansas (2), and Oklahoma (2)—371,893 tons, $501,203; Colorado (3), Montana (2), South Dakota (1), Utah (2), and Wyoming (1)—166,547 tons, $235,628; Ohio (2) and Virginia (2)—470,064 tons, $814,645.

CALCINED PRODUCTION AND PROCESSING EQUIPMENT

The calcined production in 1943 was obtained from 50 active plants distributed through 24 States. Active calcining equipment in these plants comprised 169 kettles, 8 beehive kilns, 11 rotary kilns, and 4 grinding-calcining units. The average mill value of calcined gypsum, which is a "transfer value" assigned by producers, increased 38 cents over 1942 to $5.77 per ton in 1943.

Calcined gypsum produced in the United States, 1942–43, by districts

District	1942		1943	
	Short tons	Value	Short tons	Value
New Hampshire, Vermont, Massachusetts, and Connecticut	91,788	$589,055	47,987	$358,391
Eastern New York, New Jersey, Pennsylvania, Georgia and Florida	500,011	3,390,693	183,993	1,366,383
Western New York	529,616	2,439,984	506,177	2,805,805
Ohio and Virginia	286,296	1,661,865	305,410	1,893,021
Michigan and Indiana	424,283	2,259,095	344,150	1,913,787
Iowa	324,387	1,476,107	286,855	1,435,268
Kansas and Oklahoma	159,585	853,532	191,643	1,194,097
Texas	285,430	1,202,266	275,920	1,273,305
Colorado, Wyoming, South Dakota, and Montana	73,893	446,562	88,527	584,004
Utah	20,695	122,303		
California, Nevada, and Arizona	349,098	1,961,606	327,068	1,927,526
	3,045,082	16,403,068	2,557,730	14,751,587

To meet the strong demand for board products, the 36 board machines in the country were operated at 78 percent of capacity in 1943 (capacity data are upon a time-utilized basis, in which 100 percent equals full operation for 85 percent of the total number of hours in each month). The monthly range in rate of operations was between 65 percent of capacity in January and 84 percent in June. Over-all activity of machines in Atlantic tidewater plants was well below that of machines in plants processing domestic crude. Activity of the 8 machines in Atlantic tidal plants was 49 percent of capacity and was lowest in March (39 percent) and highest in November (56 percent). The remaining 28 machines in plants not on Atlantic tidewater were operated at a monthly rate that averaged 90 percent of capacity and ranged between 86 percent in May and 94 percent in April and November. One machine in the Northeastern States was shut down early in 1943. In the board-shortage area on the Pacific coast, producers were unable to reach full capacity of machines because of the scarcity of surfacing papers in that region.

DISTRIBUTION OF SALES, BY USES

The second year of war effected further changes in the distribution of total sales value among groups of gypsum products. As illustrated in figure 2, the proportions represented by sales values of uncalcined products, building plasters (including Keene's cement), lath, and tile declined from the 1942 distribution, whereas the proportions for industrial plasters and "All other board" increased. The "All other board" group includes wallboard, sheathing, and laminated board and in 1943 represented 63 percent of the total sales value. Comparison of the 1941 and 1943 distributions shows the marked changes in composition of sales by the industry that have been caused by the war.

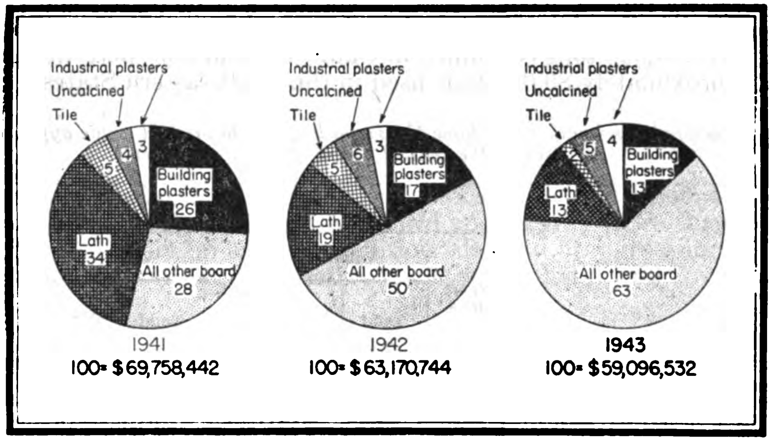

FIGURE 2.—Percentage distribution of total sales value, f. o. b. plant, of gypsum products, 1941–43, by groups of products.

A notable feature of figure 3 is the steep uptrend of the "wall- and other board" (includes wallboard, sheathing, and laminated board) curve since 1939 and the continuation of this trend through 1943 despite the slump in floor area of building. Although lath sales fell sharply in 1942 and 1943, the square footage sold in 1943 was only slightly lower than in 1929 and was far above the low point reached in 1933. The decline in total area of building in the country probably was not as severe as was indicated by the Dodge Corporation figures, which do not include construction west of the Rocky Mountains. In 1943, a larger than usual proportion of total building was in the Far West region.

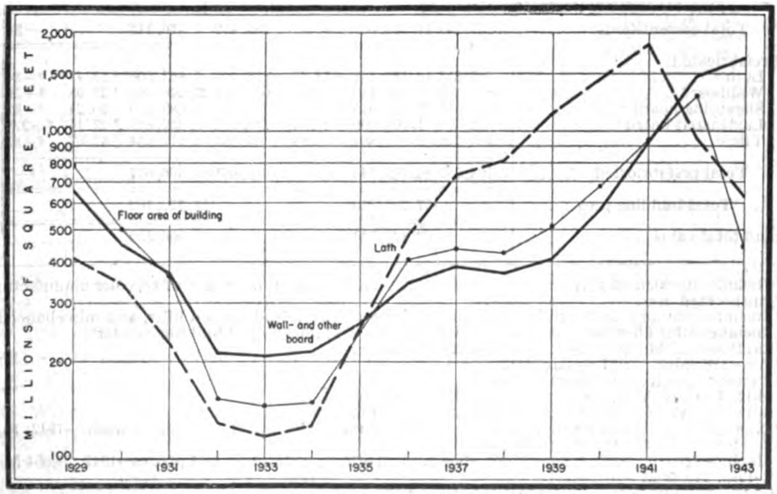

FIGURE 3.—Trends in sales of gypsum lath and wall- and other board (includes wallboard, laminated board in terms of component board, and sheathing) compared with Dodge Corporation figures on floor area of residential and nonresidential building, 1929–43.

Sales of agricultural gypsum in 1943 advanced to a record annual volume, but as this gain only partly offset the sharp decline in consumption of cement retarder the total sales of uncalcined products fell nearly one-fifth below 1942. The marked increase over 1942 in use of agricultural gypsum resulted from a 60-percent gain to approximately 293,000 tons consumed in California and a 30-percent increase to approximately 80,000 tons used in the Southeastern States.

Gypsum products (made from domestic, imported, and byproduct crude gypsum) sold or used in the United States, 1942–43, by uses

Use	1942			1943			Percent of change in—

---

[1] Includes uncalcined gypsum sold for use as filler and rock dust, in brewer's fixe, color manufacture, and for unspecified uses.

[2] Includes statuary, industrial casting and molding plasters, dead-burned filler, and miscellaneous uses.

[3] Includes joint filler, patching and painter's plaster, and unclassified building plasters.

[4] 1942: 959,307 M square feet; 1943: 630,639 M square feet.

[5] Average value per M square feet.

[6] Percent of change in square footage.

[7] 1942: 1,046,025 M square feet; 1943: 1,241,828 M square feet.

[8] 1942: 369,313 M square feet; 1943: 231,356 M square feet.

[9] New product first marketed in 1942. Square footage in terms of component board—1942: 53,170 M square feet; 1943: 200,815 M square feet.

[10] Includes partition, roof, floor, soffit, shoe, and all other gypsum tiles and planks—1942: 24,664 M square feet; 1943: 11,638 M square feet.

[11] Average value per M square feet of partition tile only.

The aggregate tonnage of industrial plasters sold in 1943 advanced 15 percent over 1942, owing to gains of varying proportions in sales of all groups. The downtrend in consumption of the plate-glass and terra-cotta group which started in the fourth quarter of 1941 was interrupted for the first time in the fourth quarter of 1943, when the tonnage sold was sharply higher than in the same period of 1942. Sales of this group closely follow trends in plate-glass production.

Sales of all classifications of building plasters except the "To mixing plants" and "Other" groups fell markedly from the 1942 volumes, and the total tonnage of all cementitious gypsum materials declined 34 percent.

The sharp reduction from 1942 in indicated consumption of tiles resulted from slumps of nearly one-third and slightly more than two-thirds, respectively, in sales of partition tiles and of a grouping of all other tile shapes (roof, floor, soffit, plank, and others).

Gypsum board and tile sold or used in the United States, 1939–43, by types

[1] Per M square feet, f. o. b. producing plant.
[2] New product first marketed in 1942.
[3] Includes partition, roof, floor, soffit, shoe, and all other gypsum tiles and planks.
[4] Per M square feet, f. o. b. producing plant, of partition tile only.
[5] Reported as area of component board and not of finished product.

PRICES

Prices of gypsum products in 1943, as indicated by the average mill values, showed a downward tendency. However, this easiness may have resulted from the absorption of the 3-percent transportation tax on sales in the Pacific coast region (except those under special rules of the Office of Price Administration) and in certain metropolitan areas where gypsum products are sold upon a delivered basis. The average plant value of agricultural gypsum was $2.25 in California, where sales were principally gypsite, and $6.28 in the Southeastern States, where rock and byproduct gypsum are used.

The following mill prices per M square feet of gypsum board products were set in Amendment 31 to Order A–1 under Maximum Price Regulation 188 for plants in Ohio, Michigan, Indiana, Iowa, Oklahoma, and Texas:

Lath	$13.00	Roof units (laminated), 1½-inch	$87.00
Wallboard, ¼-inch	20.00	Roof units (laminated), 2-inch	116.00
Wallboard, ⅜-inch	23.00	Sheathing (laminated), ¾-inch	44.00
Wallboard, ½-inch	25.00	Sheathing (laminated), 1-inch	48.00
Sheathing, ½-inch	20.00	Sheathing (weatherproof treated, laminated), 1-inch	53.00
Sheathing (weatherproof treated), ½-inch	22.50	Partition panel (laminated), 1-inch	58.00
Roof units (laminated), ¾-inch	54.00	Partition panel (laminated), 1½-inch	87.00
Roof units (laminated), 1-inch	58.00		

RECENT DEVELOPMENTS

The technical advantages and adaptability of the patented Capaco process as a means of precision casting of various nonferrous metals and alloys were described.[2] The process employs gypsum plaster as the mold material.

Use of a specially prepared gypsum product as an all-purpose desiccant has expanded markedly, and productive capacity[3] was quadrupled in 1943.

Description[4] of a new technique for the successful treatment of severe burns with plaster casts claims more rapid healing and return of motion to the injured part of the body than with other methods of treatment.

FOREIGN TRADE[5]

Virtually all of the crude gypsum imported during 1943 was from operations in Nova Scotia and New Brunswick, Canada. Slightly less than one-third of the tonnage was brought into the country during the first half of 1943, but with the easing of the shipping situation about midyear the rate of importation was accelerated, and the industry was permitted to import more than the quota set earlier in 1943. None of the Canadian crude entered ports farther south than the New York City customs district.

The small tonnage of crude from the Dominican Republic was consumed as cement retarder in Puerto Rico. As in former years, imports of gypsum products in 1943 were negligible.

Gypsum and gypsum products imported for consumption in the United States, 1939–43

[1] United Kingdom of Great Britain and Northern Ireland.

The only notable change in the export trade of 1943 was the slump in foreign shipments of gypsum board. As most of the board exports in recent years have been to the United Kingdom, the decline probably resulted from a shortage of shipping space. Demand for gypsum board to repair bombed buildings in the British Isles probably has not decreased in such marked degree as would be indicated by the data on exports from the United States.

WORLD PRODUCTION

World production of gypsum in 1943 is estimated at approximately 10 million metric tons, a slight gain over 1942. In the Western Hemisphere, the sharp declines in the outputs of the United States and Canada were offset in part by increased production in the Latin American countries, where construction was more active than in 1942. Production in European countries probably advanced over 1942 owing to increased demand for cement retarder and structural materials to repair or replace bombed buildings. Also, in England, France, and Germany the use of gypsum or anhydrite as raw material for making sulfuric acid and sulfide and sulfate chemicals doubtless gained over 1942 because of difficulties in obtaining supplies of sulfur and pyrites. The aggregate output from Asiatic countries and Australia probably increased slightly because of larger consumption as cement retarder. Total production in Africa apparently was about the same as in 1942; the declines in output from North African countries probably were compensated by gains in the South African region.

There has been a paucity of production data by countries since 1939 when war started in Europe. The only figures available for 1943 are: United States 3,517,628 metric tons, Canada 390,058 tons (sales), and Egypt 91,881 tons. Output in the United States represented approximately one-third of the world production, and is estimated to be about three times that of each of the next ranking countries—Germany and United Kingdom. Other countries with important output are, in probable order of tonnage, Spain, France, and Russia.

World production of gypsum, 1938–43, by countries, in metric tons[1]

SUMMARY

The over-all demand for lime increased in 1943 as the country passed from the construction into the production phase of the war program. Total sales of "open-market" lime advanced to 6,596,615 short tons, a new annual record that exceeded the former high set in 1942 by 8 percent. However, not all branches of the industry participated in the increased activity. Sales of agricultural, chemical, and refractory (dead-burned dolomite) lime gained over the 1942 tonnages, but sales of building lime were appreciably lower than in 1942. Demand for quicklime increased substantially, whereas that for hydrated lime rose only slightly in 1943. The war has had a marked effect on sales of the two types of lime, and in 1943 the tonnage of hydrate sold represented only 20 percent of the total compared with 26 percent in 1941, the last year of peacetime conditions. Government regulation of the selling prices of lime continued throughout 1943. Maximum prices of refractory lime were unchanged, and only a few upward adjustments for individual producers were allowed for agricultural, building, and chemical lime. The net mill realization advanced 17 cents over 1942 to $7.44 per ton in 1943.

Lime producers in all sections of the country reported operating difficulties, of which the most prevalent were short labor supply, high rate of labor turn-over, rising production costs, and low prices. The extreme shortage of labor was indicated by Bureau of Labor Statistics indexes of average monthly employment at lime plants, which were 98.7 in 1943 compared with 100 in 1939 when production was 36 percent lower than in 1943. The high turn-over rate doubtless left many lime plants with inexperienced and hence relatively inefficient labor forces. Owing to overtime rates of pay and some reported increases in basic wage rates, labor costs probably were the principal factor in the increased production costs. The rise in labor costs may be measured by the pay-roll indexes of the Bureau of Labor Statistics, which had a monthly average of 171.6 for the lime industry in 1943 in contrast with 100 in 1939. Other contributing elements were increased costs of fuels, materials, and repairs. The combination of the foregoing factors and the squeeze on producers between rising production costs and relatively rigid ceiling prices resulted in the closing of numerous plants, mostly of small capacity, in 1943. Offsetting this temporary loss of industry capacity, five portland-cement plants were converted in part in 1943 to the calcining of lime, and at a sixth it was planned to start production early in 1944.

Total demand for chemical lime gained sharply in 1943 as a result of the completion and start of production in many new war plants with large requirements for lime. Consumption of chemical lime by the various industries continued to show diverse effects of the war, and although the total increased in 1943 consumption in many of the chemical uses declined from 1942. However, most of the decreased requirements were in industries with relatively small consumption, whereas nearly all industries with large requirements—notably metallurgical, carbide, glass, insecticides, and water purification—purchased more lime in 1943. In some areas of the country, local supplies could not satisfy the demand, and chemical lime had to be shipped in from relatively distant plants.

Salient statistics of the lime industry in the United States, 1925–29 (average), 1935–39 (average), and 1941–43

[1] Selling value, f. o. b. plant, excluding cost of containers.
[2] Data not available.

The 21-percent increase in sales of metallurgical lime in 1943 over the prior record volume of 1942 resulted from the high rate of operations of the enlarged open-hearth and electric-furnace capacities of the steel industry, greatly increased consumption in Bayer alumina and magnesium plants, and the larger tonnages of metallic ores treated by flotation in 1943. Although only two magnesium metal plants use "open-market" lime, several others purchased their lime requirements early in 1943, as the processing sections of the plants were completed before the lime-calcining equipment was in place. The 75-percent gain in sales of lime for carbide manufacture was the largest proportional increase of any of the major chemical uses and resulted principally from full operation of several war plants that buy their lime supplies. Demand for lime in glass manufacture, preparation of insecticides and disinfectants, and water purification also advanced appreciably in 1943. The only major chemical uses of lime to show decreased consumption from 1942 were in the paper and tanning industries.

Sales of refractory lime (dead-burned dolomite) in 1943 advanced slightly over 1942 to set a new high annual quantity. This gain apparently resulted in part from increased use of dead-burned dolomite as a patching material in open-hearth and electric furnaces, which was indicated by the moderate decline in consumption of raw dolomite for refractory uses, as listed in the Stone chapter. The increased output of steel in 1943 also contributed to the gain in demand for refractory lime.

War restrictions on construction and the changes in types of materials used in wartime compared with peacetime building were the basic causes of the continued slump in sales of building lime. The decline from 1942 in demand for mason's lime was less severe than for finishing lime, owing to the moderate use of masonry walls in war construction because of the growing critical shortage of building lumber in 1943. Sales of finishing lime were nearly a third lower than in 1942, because prefabricated, finished materials continued to replace the "built-in" construction in war housing.

Sales of agricultural lime were 13 percent larger than in 1942—a relatively small increase compared with the 23-percent gain in cash farm income. Demand in 1943 for agricultural quicklime was unchanged from 1942, whereas that for agricultural hydrate gained one-fourth over the 1942 tonnage.

The principal war controls on the lime industry in 1943 were the price regulations of the Office of Price Administration. The permitted maximum prices on building and chemical lime were continued throughout 1943 at the March 1942 level set in Maximum Price Regulation 188. A method of adjusting ceiling prices for individual producers in cases of general shortages of lime was provided in Order A–2 of the regulation, and a few price increases were allowed after the order became effective on July 5, 1943. Prices for agricultural lime were controlled by the General Maximum Price Regulation until May 15, 1943, when it was placed under Maximum Price Regulation 386. The latter order provided three methods for computing maximum prices, and a small number of upward adjustments were permitted after the effective date of the order. Control of prices of dead-burned dolomite was removed from Maximum Price Regulation 188 and placed under Maximum Price Regulation 416, which became effective July 3, 1943. The new order set plant base prices for bulk shipments ranging from $9.30 to $9.50 per short ton and for shipments in heavy paper bags at $15 per ton.

War Production Board Conservation Order L–41, which directly affects sales of building lime through its limitations on construction, was amended several times, and the major revisions of November 1, 1943, and April 19, 1944, were somewhat more restrictive than the earlier forms.

Consumption of "open-market" lime in each of the regions of the United States has had nearly similar trends since 1928, as illustrated in figure 1. In 1943, the Middle States region had the largest consumption, although the quantity was only slightly higher than in

1942. Consumption in the Northeastern States declined slightly from 1942, but in the southern and western parts of the country it gained sharply. States included in the regions of figure 1 were selected with consideration to areas of lime consumption and other economic and geographic factors and are as follows: Northeastern—Connecticut, Delaware, District of Columbia, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont; Southern—Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia; Middle—Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin; Rocky Mountain and Pacific—Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming.

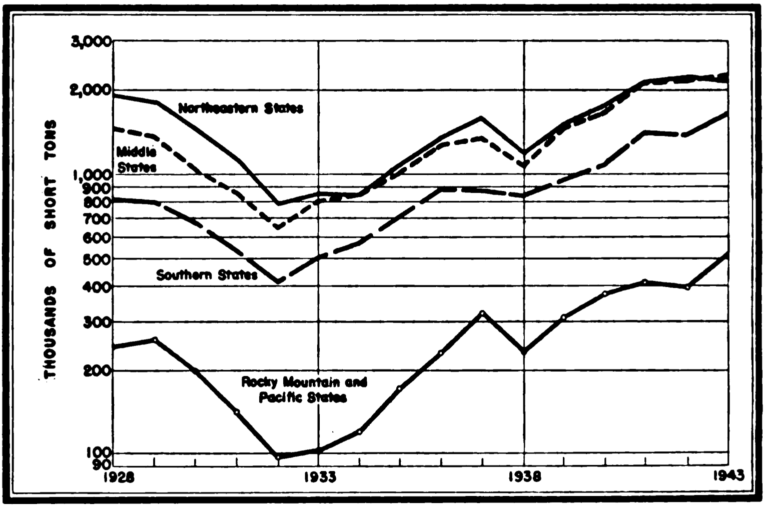

FIGURE 1.—Trends of indicated consumption of lime (including dead-burned dolomite) in the United States, 1928–43, by regions.

POST-WAR OUTLOOK

The outlook for "open-market" lime in the post-war period is encouraging, owing to some newly developed or greatly expanded uses and to increased sales to process industries that will be meeting an expectedly large backlog of civilian demand. Steel, the largest consuming industry, doubtless will require more lime for flux and refractory purposes than in the pre-war period; however, the annual requirements will be appreciably lower than during wartime. A similar situation prevails with regard to lime for carbide and alumina manufacture. The new uses in production of magnesia from sea water and of magnesium by the ferrosilicon process will have only slight upward effects, as most of the lime used in these industries falls into the captive classification. Lime requirements of the paper, glass, insecticide, water-treatment, and tanning industries doubtless will be high in the post-war era. Growing recognition of the importance of lime as a plant food and the easier availability of supplies through reopening of the many small lime plants shut down for the war should result in moderately increased consumption for agricultural purposes. The large volume of deferred construction, expected when war restrictions are removed, doubtless will raise sales of building lime well above the pre-war tonnages. All factors point toward at least a moderate gain in demand for "open market" lime over the pre-war levels.

PRODUCTION

Production of lime for each of the major uses, except building, advanced over the 1942 tonnages. Stocks reportedly are small, so that in this chapter sales are considered equivalent to production of "open-market" lime.

Lime sold by producers in the United States, 1942–43, by types and major uses

[1] Selling value, f. o. b. plant, excluding cost of containers.

[2] Includes lime used by producers (captive tonnage) as follows—1942: 427,835 short tons valued at $2,239,152; 1943: 434,571 tons, $2,457,795.

Captive tonnage.—The captive tonnage included in the figures on "open market" lime in 1943 totaled 434,571 short tons valued at $2,457,795. This total comprised 8,353 tons for masonry mortars, 325,517 tons for metallurgical uses (slightly more than half for ore concentration and the remainder for steel flux), 12,636 tons for minor chemical uses, and 88,065 tons of refractory lime.

PRODUCTION, BY STATES

The effects of the war on the location of lime production, noted in 1942, were more pronounced in 1943. The record output of 1943 was obtained from 245 plants in 36 States and 2 Territories. Compared with 1942, production gained in 19 States, declined in 14 States and 2 Territories, and was relatively unchanged in 3 States. No lime was produced in Rhode Island in 1943.

[1] Excludes bleach used in paper mills.

[2] Included under "Undistributed."

[3] Includes chocolate, cocoa, fruit juices, phosphate baking powders, and unspecified food products.

[4] Includes flotation, cyanidation, bauxite purification, and magnesium manufacture.

[5] Includes mold coating and unspecified.

[6] Includes bleach used in paper mills.

[7] Includes alcohol, bromine, calcium carbonate (precipitated), cement manufacture, chloropicrin, dicalcium phosphate, glycerin, nicotine, photographic supplies, retarder, rock wool, starfish control, sulfur, and wool pullers.

[8] Includes lime used by producers (captive tonnage) as follows—1942: 427,635 short tons, valued at $2,239,152; 1943: 434,571 tons, $2,457,795.

PRODUCTION, BY USES

Production of lime for its varied uses in 1943 showed considerable deviation from the usual peacetime pattern, and although there was an over-all gain above 1942, declines were numerous for uses in industries related closely to civilian demand.

Lime and other liming materials used in agriculture.—The total effective lime content of all agricultural liming materials sold in 1943 increased 6 percent over 1942 owing to the program carried out under the War Foods Campaign. Indicated consumption of hydrated lime, crushed oystershells, and limestone (agstone) advanced over 1942, whereas that for quicklime was unchanged, and for marl it declined.

Agricultural lime and other liming materials sold by producers in the United States, 1942–43 by kinds

Kind	1942				1943			
	Short tons		Value		Short tons		Value	
	Gross	Effective lime content [1]	Total	Average	Gross	Effective lime content [1]	Total	Average
Lime:								
Quicklime	184,678	156,980	$950,374	$5.15	184,028	156,420	$1,092,898	$5.94
Hydrated lime	215,953	151,170	1,568,579	7.26	270,105	189,070	2,041,763	7.56

Calcareous marl	194,878	81,850	135,046	.69	147,153	61,800	152,821	1.04

[1] Effective lime contents as follows: Quicklime, 85 percent; hydrated lime, 70 percent; limestone and oystershells, 47 percent; calcareous marl, 42 percent.

[2] Figures supplied by Fish and Wildlife Service.

[3] Preliminary figure.

Building lime.—The output of building lime continued to slump because of the strict curtailment of construction; the total produced in 1943 was only slightly higher than in 1934, the low point for building lime in the depression of the 1930's. Production of all classes of building lime declined in 1943.

Chemical and industrial lime.—Metallurgical industries, which were unusually active in 1943, required 29 percent of the total lime output. Sales of lime for paper making, the second largest use in 1943, declined 10 percent from 1942 because of the decreased activity in that industry owing to the pulpwood shortage. The greatly expanded use of acetylene gas for welding and synthetic rubber resulted in a 75-percent gain in sales of "open market" lime for carbide manufacture in 1943.

HYDRATED LIME

Production of hydrated lime in 1943 represented 20 percent of the total output compared with 21 percent in 1942 and 26 percent in 1941, the last year of peacetime conditions. One hundred sixty-five plants in 35 States and 2 Territories were active in 1943, and production gained over 1942 in 19 States, declined in 11 States and 2 Territories, and was virtually unchanged in 5 States.

Hydrated lime sold by producers in the United States, 1942–43, by States

[2] By groups of States as follows—1942: Maine (2 active plants), Vermont (2), Rhode Island (1), Connecticut (1), and New Jersey (3), 53,086 short tons, valued at $381,529; North Carolina (1), Louisiana (1), Arkansas (2), and Oklahoma (3), 31,374 tons, $294,885; Wisconsin (7), and Minnesota (2), 22,776 tons, $173,587; Colorado (1), Utah (2), and Arizona (2), 12,130 tons, $157,508; and Nevada (1), Montana (1), Washington (2), and Oregon (1), 19,697 tons, $208,003. 1943: Maine (2), Vermont (2), Connecticut (1), and New Jersey (3), 46,672 tons, $310,770; North Carolina (1), Louisiana (1), Arkansas (2), and Oklahoma (1), 22,917 tons, $182,324; Indiana (3), Wisconsin (6), Minnesota (1), South Dakota (1), Colorado (1), Utah (2), and Arizona (2), 59,600 tons, $507,802; and Nevada (1), Montana (1), Washington (2), and Oregon (1), 22,138 tons, $248.092.

Uses.—The decreased demand from 1942 for hydrate used in building and paper making was more than compensated for by the increased output for agricultural, metallurgical, insecticide, and water-purification uses.

TRENDS IN PRINCIPAL USES

Sales of "open-market" chemical lime since 1932 have trended upward strongly in each year except 1938, when a minor recession occurred. It is notable that the tonnage of chemical lime sold in 1943 was only slightly lower than the average total annual sales by the industry during 1925–29. The uptrend in use of refractory lime (dead-burned dolomite) continued throughout 1943, although at a lower rate of increase than in any year since 1938. The sharp decline in sales of building lime during 1942–43 to depression levels and the comparatively even trend in demand for agricultural lime are illustrated in figure 2.

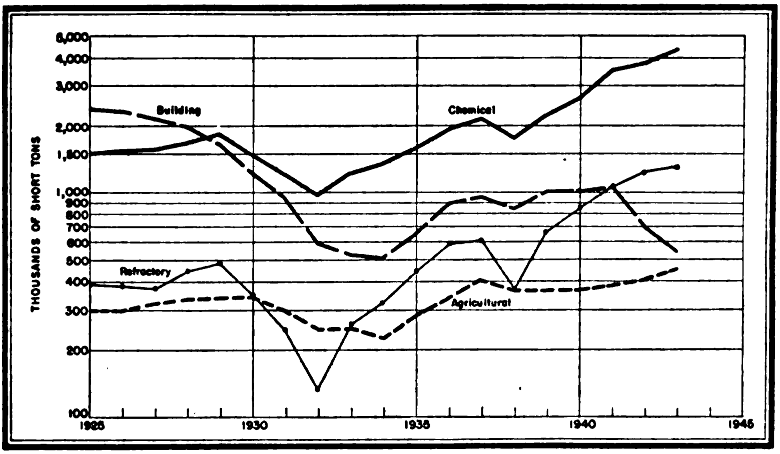

FIGURE 2.—Trends in major uses of lime, 1925–43.

SHIPMENTS

Total shipments.—Output exceeded apparent consumption in 12 of the 36 lime-producing States in 1943. However, the excess of out-of-State over into-State movements represented large tonnages only in Missouri, Ohio, Tennessee, and West Virginia. Indicated consumption in Pennsylvania in 1943 was much larger than in any other State, and the supply from local lime plants fell about 100,000 tons short of requirements. The other ranking States, in order of tonnage consumed, were Ohio, Illinois, and New York.

Sales, shipments, and supplies of lime available for consumption in continental United States, by States and groups of States, are listed in the two following tables.

Lime supplies available in continental United States in 1943, by States, in short tons

State	Sales by producers	Shipments from State[1]	Shipments into State	Supply

[1] Less than 0.1 percent.

MILL VALUES

The net mill realization (excluding container cost) per ton of lime sold in the open market in 1943 averaged $7.44, a gain of 17 cents over the 1942 figure. This increase apparently resulted principally from the scattered price increases allowed by the Office of Price Administration to producers whose costs had risen in such degree that production could not be maintained without higher prices. In 1943 the net mill value per ton of both quick and hydrated lime increased over 1942 for each of the major uses except building, for which the values declined slightly.

NEW DEVELOPMENTS

The combination of a traveling-grate stoker-coking unit with a rotary limekiln in a carbide plant has been successful.[1] Coke is produced in the stoker, and the large volume of hot, relatively low B. t. u., combustible gases pass directly into the rotary kiln. The lime is soft-burned, and ring formation in the kiln is virtually absent. Maximum heat utilization is attained through use of waste-heat boilers.

Results of research on the measurement and determination of the physical properties of lime that are desirable for the various uses of lime were described.[2]

SIZE OF PLANTS

The effects of the war on lime plants with small annual production are illustrated by the data on groupings of plants according to size of output. As reported by producers, the labor shortage and the squeeze between rising production costs and ceiling prices have been the principal reasons for closing many of the plants that shut down during 1942 and 1943. From the figures below, it is apparent that most of the shut-downs have been in the small size groups. In 1943 the number of plants in each group under 25,000 tons of annual production was less than in 1942 and 1941, whereas in the groups over 25,000 tons the number of plants increased. Five cement plants that were converted in part to lime production are included in the 1943 data. The aggregate output of all plants producing less than 25,000 tons was only 15 percent of the total lime production in 1943.

Distribution of lime (including refractory) plants, 1941–43, according to size of production

Size group (short tons)	1941			1942			1943

CLAYS

By G. W. JOSEPHSON AND A. LINN[1]

SUMMARY OUTLINE

	Page		Page
General summary	1369	Fire clay	1376
Salient statistics	1370	Bentonite	1377
Post-war prospects	1370	Fuller's earth	1379
Consumption and uses	1371	Miscellaneous clay	1380
China clay or kaolin	1372	Clay products	1382
Ball clay	1374	Technologic developments	1382

GENERAL SUMMARY

As the United States reached peak rates in the production of military equipment the output of some clays likewise expanded, whereas others declined. In wartime, commodities may rise to boom levels and slump to the depths of depression in a matter of months. During the construction period almost all clays reached new highs. Heavy-clay products were in great demand for factories and housing; without fire-clay refractories the expansion and maintenance of the high-temperature industries would have been virtually impossible; bentonite, kaolin, ball clay, and fuller's earth all made substantial contributions through old and new uses.

In 1943 construction was nearing completion, and emphasis shifted to military production. Demand for building brick and other heavy-clay products was reduced to a point so low that many plants closed for the duration. Others found great difficulty in continuing in the face of increased costs and manpower shortages.

On the other hand, some clays fared very well. Fire-clay requirements declined slightly as building programs in the metal, power, and glass industries reached completion. Maintenance will continue to consume refractories at a high rate. Markets for kaolin and ball clay contracted somewhat but still compared favorably with pre-war standards. Bentonite, finding a larger market in foundries and oil-well drilling, established a new sales record, and fuller's earth regained much of the volume lost since 1930.

The security of foreign shipping is ordinarily of little consequence to the clay industry. The United States has ample supplies of all types of clay, and imports are limited to certain specialties, such as English ball and china clays. Moderate tonnages of fire clay, bentonite, and other high-quality domestic clays are exported. Notwithstanding a great improvement in the shipping situation in 1943, both exports (163,539 tons) and imports (71,478 tons) were lower than in 1942.

---

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the United States Department of Commerce.

Shipping problems have had special significance for clay during the past 2 years because interest in the use of clay as an ore of aluminum stems from the fact that the United States depends on Surinam for most of its bauxite. As shipping in the Caribbean became more secure and an over-supply of aluminum accumulated, large-scale programs designed to produce the metal from clay lost much of their impetus. On the other hand, many people continued to advocate the further development of the processes on a plant scale as a guarantee of future safety. At the end of the year plant erection was proceeding.

Prices of fire and common clays remained under the provisions of Maximum Price Regulation 188, and on February 16, 1943, kaolin, bentonite, and fuller's earth were placed under MPR 327. A subsequent amendment also placed ball, slip, and stoneware clays under the latter. These regulations continued the ceiling prices established by the General Maximum Price Regulation and outlined procedures through which producers could obtain relief. In a few instances, adjustments were granted to individual companies, but no general rise in prices was approved by the Office of Price Administration.

[1] Does not include clay burned into clay products in integrated plants at mine or pit.

POST-WAR PROSPECTS

Although clay will face strong competition from other building materials, both old and new, it probably will retain a substantial part of its present popularity in home and industrial construction during the years immediately after the war. However, new materials and fabrication methods are being developed at a rate that constitutes a challenge to clay over a period of years, and much will depend on the vigor with which clay products manufacturers meet rival claims of advantages in insulating value, price, appearance, and convenience. Unquestionably there is an accumulated demand for new homes that can reach boom proportions over an extended period if financial conditions are favorable.

When armament production is reduced, the volume of fire clay consumed is certain to decline, but it may not drop to pre-war levels. Bentonite and fuller's earth are also closely geared to war production and are likely to decrease, although expanding acceptance of these in new uses may largely counteract other losses.

Under prosperous conditions kaolin and ball clay may retain most of their 1943 volume in spite of the fact that unlimited quantities of imported clays again will be available.

Substantial markets will exist for all the clays in the post-war period, and if adequate purchasing power is available the outlook is favorable.

CONSUMPTION AND USES

The accompanying table, which gives sales of specified domestic clays by kinds and uses for 1943, continues a series begun in 1921. Trends in the use of individual clays during the past 10 years are also shown by charts on other pages of this chapter. The consumption of all clays, including both captive and merchant types, totaled about 23,000,000 tons in 1943.

Clay sold or used by producers in the United States in 1943, by kinds and uses, in short tons

[2] Comprises following: Mineral oils, 218,423 tons; vegetable oils, 19,429 tons.

CHINA CLAY OR KAOLIN

Although shipments of kaolin declined 2 percent in tonnage in 1943 they were higher than in any previous year except 1941 and 1942 and were 42 percent greater than the 1935–39 average.

In 1943 Georgia alone supplied 79 and South Carolina 12 percent of the total output, the same percentages as in 1942. The remaining 9 percent was shared by 11 States.

Consumption by uses was very much the same as in 1942. Paper consumed 59 percent, refractories 16, pottery 9, rubber 5; and a variety of industries, such as chemicals, paint, and linoleum, absorbed the remaining 11 percent. Restrictions on the production of some types of paper, owing to emphasis on the strong packaging papers that require no kaolin, kept this market slightly below the peak attained in 1941, but the volume of paper-clay sales was still 18 percent higher than the 1939 level. Although lower than in 1941, sales of pottery kaolin were 78 percent greater than the average of the 5 years ended in 1939. Refractory kaolin continued in demand at more than double the pre-war volume; but as compared with 1942, 8 percent less was sold.

Although sales of kaolin for rubber compounding were virtually the same in 1942 and 1943, there is evidence that some ground was lost. Rubber fabrication was sharply reduced in 1942 and then increased, as more and more synthetic rubber became available in 1943. Therefore, less clay was used per unit of rubber manufactured in 1943. Part of this reduction may be explained by the fact that manufacturers are now prohibited from making many products that ordinarily require large quantities of filler, and resumption of this output will automatically benefit clay. On the other hand, synthetic rubber now requires the incorporation of certain reinforcing compounds, principally carbon black, in preference to clay-type fillers. However, synthetic rubber processing is undergoing rapid development, and future discoveries may change present practice completely. It is apparent that research and post-war policies on importation of natural rubber will have a profound effect on the market for kaolin in the rubber industry.

Prices of kaolins vary widely. Crude can be had for as little as $2.50, and special products may reach $40 per ton. Most of it sells between $6 and $15 per ton, depending on such factors as quality, degree of preparation, and location. The national average value reported by producers to the Bureau of Mines was $8.68 per ton, somewhat higher than in 1942 ($8.49). English kaolin, c. i. f. American ports, was quoted, lump $19 to $28 per long ton and air-floated $40 to $60.

China-clay imports have decreased steadily from 114,696 tons valued at $1,015,813 in 1939 to 55,565 tons valued at $584,532 in 1943. All but 737 tons that entered from Canada came from the United Kingdom. Kaolin serves as satisfactory ballast for ships

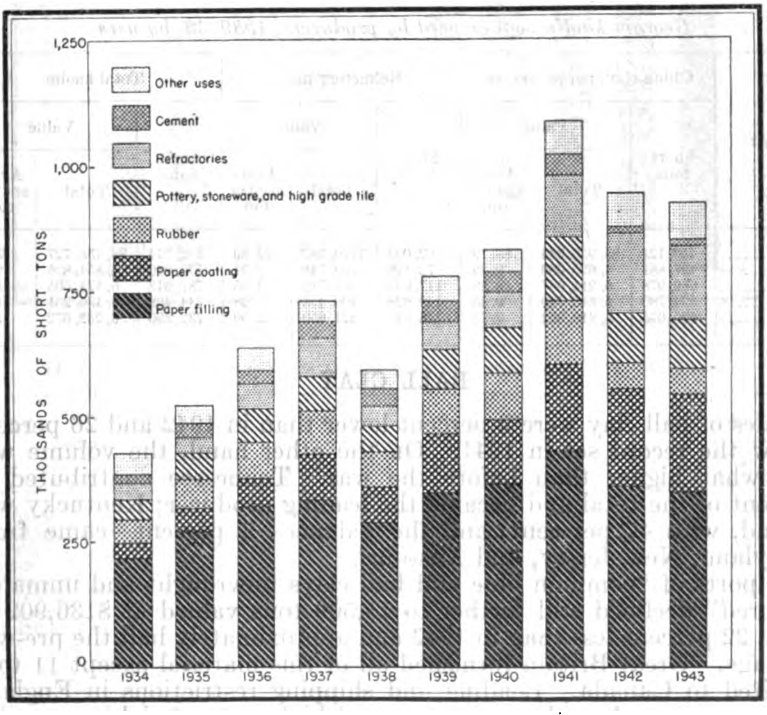

FIGURE 1.—Kaolin sold by domestic producers for specified uses, 1934–43.

returning from Britain, but routing problems and the danger of bombing while ships were detained in the war zone reduced the number of bottoms assigned to the transportation of relatively noncritical materials. English kaolin was included on the list of strategic raw materials by the Army and Navy Munitions Board because it is considered to be necessary in the production of high-quality ultramarine blue pigment, but this use represents only a small tonnage.

BALL CLAY

Sales of ball clay were 9 percent lower than in 1942 and 26 percent below the record set in 1941. On the other hand, the volume was somewhat higher than before the war. Tennessee contributed 48 percent of the total and became the leading producer; Kentucky was second, with 47 per cent; and the balance—5 percent—came from Maryland, New Jersey, and Missouri.

Imports of "common blue and ball clays unwrought and unmanufactured" declined still further to 15,509 tons valued at $136,902 in 1943, 22 percent less than in 1942 and approximately half the pre-war tonnage. Great Britain furnished all of this material except 11 tons credited to Canada. Loading and shipping restrictions in England have contributed to the reduction, and high ocean freight costs give American ball clays an additional advantage in wartime. The average price of the imported material before shipping costs were added was $8.83 in 1943, somewhat lower than the $9.21 per ton reported in 1942.

Trade journals quoted Kentucky-Tennessee ball clay at $7, with air-floated bringing $14 and up. Maryland ball clay, shredded, bulk, brought $3 to $7 per ton, and air-floated, in paper bags, $10 to $18.25. The average value as reported by producers to the Bureau of Mines was $8.60 per ton, only slightly higher than the $8.49 obtained in 1942.

Although ball clay serves a useful purpose in a number of other products, such as linoleum, refractories, and asbestos, over 90 percent was consumed in pottery and 5 percent in high-grade tile. Much of the domestic ball clay is burned in New Jersey and Ohio potteries, whose high-grade products are sold throughout the country. Some interest is being shown in the development of potteries close to the source of raw material supply to reduce transportation cost on ware marketed in the Southern States.[3]

FIRE CLAY

Consumption of fire clay began to taper off in 1943. Demand was still extremely high, by peacetime standards, but construction programs were reaching completion in the metal and other high-temperature process industries. The total output of fire clay (including both that shipped as raw clay and that burned into clay products at the mine or pit) declined 6 percent—from 8,296,745 tons in 1942 to 7,798,233 tons in 1943. The portion shipped as raw clay dropped only 3 percent, indicating that refractories producers tended to use the available labor in the plant while drawing their raw clay from more distant pits.

Fire clay is widely distributed, but quality and market advantages tend to concentrate activity in a few States. Shipments were reported from 30 States. Missouri contributed 26 percent, Pennsylvania 25, Ohio 17, California 8, Kentucky 7, Illinois 4, and New Jersey 2; these seven States supplied nearly 90 percent of the shipments in 1943 and about 84 percent of the total fire clay produced.

Although the physical and chemical properties of the fire clays enable them to find a use in a variety of commodities, such as heavy-clay products, pottery, fillers, and chemicals, 90 percent was consumed in refractories in 1943.

Unlike most other clays, exports of fire clay have been maintained at a comparatively high level during this war. The United States Department of Commerce reports that none was imported, but

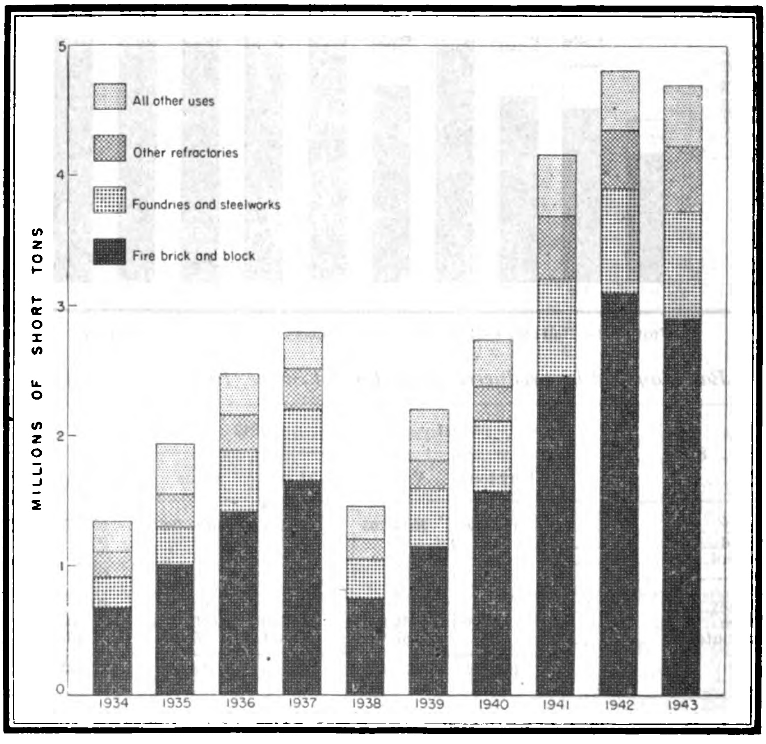

FIGURE 3.—Fire clay sold by domestic producers for specified uses, 1934–43.

97,362 tons valued at $636,079 were exported in 1943, somewhat less than the 118,101 tons of 1942 but more than the 91,732 tons of 1941. In contrast, only 66,177 tons of all other clays combined were exported in 1943.

BENTONITE

The rapid growth in the use of bentonite continued in 1943, and a new record was attained 28 percent greater than the previous high (set in 1942). Demand increased in most uses. Foundries and steelworks took 21, filtering and decolorizing oils 36, and expanded oil-well drilling programs 41 percent more than in 1942. Decreases were reported in some minor uses, but they were far overshadowed by the expansion in the large consuming industries. Of the total sales, foundries and steelworks consumed 38, filtering and decolorizing oils 33, and rotary drilling mud 14 percent—a total of 85 percent.

Output increased in all seven producing States. The popularity of bentonite from the Wyoming-South Dakota area is demonstrated by the fact that these two States supplied 59 percent of the total tonnage and 74 percent of the value in 1943. Wyoming was the leading producer, with 33 percent of the national total. Shipments from South Dakota were 41 percent greater than in 1942, continuing an expansion that has seen output grow from 20,565 tons in 1938 to 124,528 in 1943.

As production has increased the average value has decreased, partly owing to reductions in price but also because of the great expansion in use of the lower-priced grades. Trade journals quoted Wyoming dried and crushed bentonite at $7.50 per ton; pulverized, 200-mesh,

$9.50 to $11; and 325-mesh, bagged, $16. Most mine-run material is valued from $2 to $5 per ton, and at the other extreme very finely pulverized products may bring up to $35 per ton. The average value reported by producers in 1943 was $6.24, substantially less than the $6.80 recorded in 1942.

The records of the United States Department of Commerce show that no bentonite was imported in 1943. Export statistics on bentonite are not recorded separately, but producers reported to the Bureau of Mines that they exported 6,400 tons in 1943. This tonnage does not include dealer exports and acid-treated bentonite shipped to foreign oil refineries.

FULLER'S EARTH

Assisted by expansion in new uses and shortages in the supply of competitive products, shipments of fuller's earth in 1943 were 33 percent greater than in 1942. Mineral oil refining consumed 80 percent and vegetable oil 7 percent of the total tonnage.

As indicated in figure 5, the consumption of fuller's earth declined sharply from 1930 to 1940. Its principal market—oil refining—was expanding, but improved refining methods and increased use of colored gasoline combined with strong competition from activated bentonite, bauxite, and synthetic magnesium silicate to reduce sales steadily.

The recovery in volume since 1940 has been attributed to a combination of factors, such as increased consumption per unit of petroleum product, owing to earlier rejection of fouled earth, and restrictions in the supply of competitive materials. Fuller's earth benefited from the enlarged oil-refining program, even though the expansion shown on the accompanying charted curve of petroleum-refining activity has been due largely to aviation gasoline and butadiene production, neither of which is a process consuming large quantities of fuller's earth.[3] If these are excluded an index number of 120 is attained for 1943. Fuller's earth finds some use as a catalyst as well as a decolorizer. In 1943 producers also reported that a substantial and increasing tonnage was sold for various adsorbent uses, for example, on the floors of machine shops.

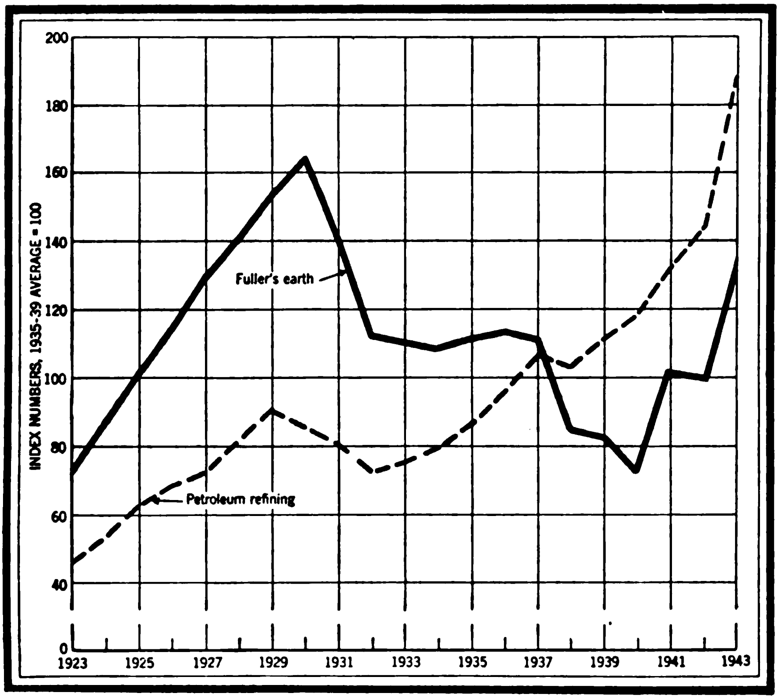

FIGURE 5.—Mine shipments of fuller's earth compared with petroleum-refining activity (Federal Reserve Board Index), 1923–43.

---

[3] Information furnished by Petroleum Administration for War.

Texas was again the principal producer of fuller's earth, with 35 percent of the total tonnage. Georgia and Florida together supplied 39 percent and Illinois 24.

Whereas the value for the entire country was $10.56 per ton in 1943 ($10.48 in 1942), material from the Georgia-Florida district averaged $13.68, from Illinois $9, and from Texas $7.73.

Many fuller's earth products require considerable preparation to fit them for the intended application; therefore prices vary widely according to the cost of processing—from about $5.50 to $16 per ton. The variation is illustrated by current trade-journal quotations for Georgia-Florida material—30- to 60-mesh, $14.50; 15- to 30-mesh, $14; 200-mesh up, $10; 100-mesh up, $7.

Imports of fuller's earth in 1943 sank to 157 tons valued at $2,154, all from the United Kingdom. Before the war imports commonly ranged from 1,500 to 5,000 tons per year, but since 1940 they have not exceeded 500 tons.

Exports are not separately recorded by the United States Department of Commerce, but producers reported to the Bureau of Mines that 6,842 tons valued at $59,485 were shipped to Canada, the West Indies, and the Persian Gulf in 1943, approximately the same quantity as in 1942 (6,052 tons) but somewhat below the pre-war level (up to 11,000 tons yearly).

Fuller's earth sold or used by producers in the United States, 1941–43, by States

State	1941		1942		1943	
	Short tons	Value	Short tons	Value	Short tons	Value
Florida and Georgia	91,925	$1,075,318	83,007	$1,091,062	105,647	$1,444,936
Illinois	26,676	209,577	30,421	264,611	63,909	575,805
Texas	77,033	713,085	85,012	712,303	94,137	728,141
Other States [1]	11,812	113,694	5,804	71,694	7,974	118,926
	207,446	2,111,674	204,244	2,139,670	271,667	2,867,808

[1] Comprises the following: California, Colorado (1942), Nevada, New Mexico (1941), Tennessee (1941 and 1943), and Utah.

MISCELLANEOUS CLAYS

In addition to the generally recognized classes discussed in the foregoing sections of this chapter, other clays are grouped as miscellaneous owing to limited use or lack of uniform definition of their properties. The greater part of this tonnage consists of the common clays and shales used in making heavy-clay products and cement. Small quantities of slip clay are included, and the remainder is consumed in rotary drilling and for other purposes as outlined in the table of uses.

Most of this material is valued at less than $1 per ton; but some of the higher-priced products, such as slip clay and rotary drilling mud, are worth from $4 to over $10 per ton.

For a number of years the Bureau of Mines has emphasized that portion of the total output that was sold as raw or prepared clay or shipped by the mining company some distance to a plant before being converted into a salable product. Some statistics were gathered on clay burned into products at plants at the mine or pit, but only incidentally to the canvass of merchant clays. This practice gave an accurate measure of kaolin, ball clay, bentonite, fuller's earth, and even fire clay, as a substantial percentage of each is sold after comparatively little preparation, and the captive tonnage was also reported by the producers.

On the other hand, most of the clay used in the production of common brick, sewer pipe, and other heavy-clay products is mined close to the kilns and does not enter the market until it has been burned. Figures on this great tonnage have been intermittent or incomplete. In an attempt to fill this undesirable gap in the statistics of the clay industry the Bureau of Mines expanded its 1943 canvass to include this type of operation.

Similarly, most of the clay and shale used in the manufacture of cement is mined by the cement companies at nearby pits. The cement industry reported to the Bureau of Mines that it used 4,004,316 tons of clay and shale in 1943.

From reports of producers, substantiated by calculations based upon clay products figures furnished by the War Production Board, the total of "miscellaneous" clays consumed in 1943 was about 14,000,000 tons.

As shown by the accompanying table, the merchant clay portion comprised only a small fraction of this total. Being less dependent on the construction industry, it experienced a smaller decline in 1943 (17 percent) than did the captive tonnage. This is indicated by the fact that the cement industry required 23 percent less than the 5,181,582 tons it used in 1942, and the clay products output was little more than half as great as in the previous year. Sales of miscellaneous clays for use as drilling mud were 52 percent larger than in 1942.

Miscellaneous clay, including slip clay [1] *and shale, sold or used by producers in the United States, 1941–43, by States* [2]

State	1941		1942		1943

	1,210,168	1,402,592	1,019,663	1,177,474	850,397	1,280,452

[1] Includes slip clay as follows—1941, 5,649 short tons, valued at $40,797, from Kentucky, Michigan, New York, Ohio, and Pennsylvania; 1942, 5,164 tons, $41,856, from Michigan and New York; 1943, 5,386 tons, $47,386, from Michigan and New York.

[2] Does not include clay burned into clay products in integrated plants at mine or pit.

[3] Included under "Other States."

[4] Includes States indicated by "(3)" above, and Connecticut (1941–42), Georgia, Kansas, Kentucky, Louisiana, Maryland, Massachusetts, Michigan, Minnesota, Mississippi, Montana, Nevada (1941), New Jersey, New Mexico, New York, Oklahoma, Oregon, Tennessee, Utah, and Wisconsin.

CLAY PRODUCTS

Demand for structural clay products dropped to a low point in 1943. War-plant building was nearing completion, and home construction was restricted by wartime limitations on the manufacture and use of many essential components. House construction was encouraged only in certain areas, particularly around war plants, where existing facilities were inadequate to handle the expanded population.

Clay products manufacturers had great difficulty in finding enough manpower to satisfy even the reduced demand, and inventories of brick dropped from 889,000,000 to 425,000,000 during the year. Many companies closed their plants for the duration of the war.

As indicated in the accompanying table, in 1943 the production of glazed and unglazed common and face brick, unglazed hollow facing tile, and unglazed structural tile was only 43 percent as high as in 1941, and the industry operated at about 21 percent of capacity.

Data on building brick and clay tile in the United States, 1940–43 [1] [2]

[Millions of brick or brick equivalent]

[1] Abstracted from reports issued by War Production Board.

[2] Includes glazed and unglazed common and face brick, unglazed hollow facing tile, and unglazed structural clay tile. Sewer pipe and paving brick not included.

[3] Figures not available.

TECHNOLOGIC DEVELOPMENTS

In 1942 and early 1943 there was every indication that some of the processes by which aluminum can be derived from the aluminum silicates would have an opportunity to prove themselves on a commercial scale. Then submarine sinkings decreased, and it became evident that bauxite from Surinam was no longer likely to be cut off during this war. Simultaneously, stocks of aluminum began to mount until there was finally an oversupply despite the tremendous requirements of the aircraft industry.

Under these conditions new capacity was not welcome, and resistance to the clay program developed. Its advocates stressed the advantages of future national security to be gained, and at the end of the year erection of three plants was in progress or in preparation. Clay is to be the ore used by Ancor Corporation in South Carolina and by Columbia Metals Corporation in Oregon, whereas Monolith Portland Midwest Co. intends to use feldspar in Wyoming. The Ancor and Monolith plants are designed for lime-soda extraction and Columbia for the ammonium sulfate process.

Kalunite, Inc., which is now producing alumina from alunite in Utah, may also enter the clay field in the future.

In past years comparatively few clay products manufacturers have considered themselves in a position to conduct extensive research programs. Refractories producers have made real progress both in quality and processing methods, and these advances have been of great benefit in war production.[4] Additional interest is also developing among the manufacturers of heavy-clay products. Some companies that cannot afford full-scale research in their own plants can obtain vital information through cooperative action in trade associations [5] or through financial support of specific projects in universities or research institutes. Particular stress is being placed on maintaining the utility and economy of standard shapes in modern construction and the development of new products or designs to meet the competition of such materials as plywood, plastics, glass, and light metal, all of which hope to gain a larger portion of the building-material market after the war.

GENERAL CONDITIONS

The total value of products of the industries producing natural abrasives increased about 3 percent in 1943 compared with 1942. Garnet, emery, quartz, and ground sand and sandstone in 1943 had substantially higher values than in 1942. The value of ground sand and sandstone was the highest on record, and the values for garnet, emery, and quartz were the largest since 1929, 1918, and 1919, respectively. The values of the other products for which figures are given showed large decreases.

Salient statistics of the abrasives industries in the United States, 1942–43

	1942	1943	Percent of change in 1943
Domestic production (sold or used by producers):			
Natural silica abrasives:			
Diatomite	(1)	(1)	
Tripoli	$272, 428	$244, 365	−10
Quartz	331, 494	346, 558	+5

---

[1] Bureau of Mines not at liberty to publish figures. Average for diatomite for 1939–41 was $1,915,405.

[2] Excludes value of corundum, diatomite, and oilstones and related products, which the Bureau of Mines is not at liberty to publish.

[3] Includes material produced in Canada; Bureau of Mines not at liberty to publish United States data separately.

[4] Revised figure.

The greatly increased need for abrasives in the enlarged industrial program stimulated by the war caused a corresponding rise in the production of crude manufactured (artificial) abrasives—silicon carbide, aluminum oxide, and metallic abrasives. All records were surpassed in both quantity and value by comparatively large margins. The combined total output of these materials, largely used for abrasive purposes, totaled 17 percent higher in tonnage and 13 percent more in value than in 1942, the former peak year. Production of aluminum oxide and silicon carbide was at virtual capacity (98 percent), and that of metallic abrasives at about 73 percent of capacity. Each class of product separately also established record outputs in 1943. Percentages of increase in tonnage in 1943 compared with 1942 were: Metallic abrasives (chilled iron and steel shot and grit), 17 percent; aluminum oxide, 18 percent; and silicon carbide, 13 percent.

The total value of imports of natural abrasive products into the United States was only slightly under the high figure reported in 1942. Imports of industrial diamonds (largely comprised in the classification "glaziers' and engravers', unset, and miners' diamonds") in 1943 surpassed by 8 percent the record-breaking year 1942, although the average value per carat declined 8 percent, indicating the increased consumption of smaller stones. There was a very large rise in imports of diamond dust. Corundum receipts in 1943 were 20 percent higher than in 1942 and only 3 percent under the peak (since 1924) year 1941. Pumice imports were small, as were those of tripoli and rottenstone. The total value of exports of abrasive products decreased 47 percent in 1943 compared with 1942, owing chiefly to the sharp drop in 1943 in the value of exports of emery and corundum wheels.

This chapter includes data for most of the materials used chiefly as abrasives, although certain clays, oxides, and substances mentioned later under "Miscellaneous mineral abrasive materials" are not included in the statistics presented herein. On the other hand, certain of the "abrasive materials" for which figures are shown also have important nonabrasive uses.

POST-WAR PROSPECTS

Although some recession may occur, at least during the change-over to a nonmilitary economy, the large backlog of potential demand for civilian housing and civilian goods of a wide variety undoubtedly should affect favorably the production and consumption of the products of the industries included in this chapter, with respect both to their abrasive and their nonabrasive uses. The resumption of full-scale manufacture of private automobiles and many other articles of domestic consumption will tend to cushion the cessation or, at least, the large reduction in manufacture of munitions, ships, and other war matériel. Not only will articles similar to pre-war goods be made, but also products or adaptations of the intensive research and development programs sponsored in connection with war activities. As virtually all modern industrial manufacturing operations are dependent upon abrasives at some stage in processing, and many industries employ abrasive materials for cutting, grinding, and polishing, those products having abrasive uses, as a whole, should follow the general trend of business activity in the days after the war.

In the post-war world, the market for insulation media, in particular, probably will expand greatly. The projected large increase in manufacture of air-conditioning equipment and its installation in private housing and public buildings should lead to the more general use in new construction of insulating materials for protection against heat in summer and cold in winter, as well as to achieve the evenly regulated temperatures required for optimum efficiency in many industrial operations. Diatomaceous earth and, to a lesser extent, pumice would be affected by this development. These two mineral substances also should be advantageously affected by the resurgence of private construction, as the use of diatomite in concrete and lightweight aggregate was growing when building was curtailed by Government order; and comparatively large quantities of pumice normally are employed in building operations, particularly in Western States. In high-temperature refractories and in the filtration of many liquids, diatomaceous earth also would share in the post-war market.

The diamond has attained such vast importance in war industry that a highly active demand for industrial grades should persist beyond the war period.

NATURAL SILICA ABRASIVES

Diatomite.—The Bureau of Mines has not been at liberty to publish annual production data for diatomite since 1926. Total output (sales) for 3-year periods, however, may be shown. Total sales for the three most recent of such periods were as follows: 1939–41: 360,502 short tons valued at $5,746,216; 1936–38: 279,645 tons valued at $4,377,353, and 1933–35: 244,342 tons valued at $3,618,428. Sales of diatomite in 1943 were somewhat higher in quantity and value than in 1942.

California and Oregon remained the principal producing States. Diatomite also was produced for sale in Florida, Idaho, Nevada, New Mexico, New York, and Washington.

Approximately the same distribution, according to percentages of total diatomite sales in 1943, prevailed for uses as in 1942—about half for filtration, one-quarter for insulation, one-sixth for fillers, and the remainder for miscellaneous uses, including small amounts for abrasives. In 1943, however, the figure for insulation was slightly under the 1942 percentage.

Quotations for diatomite throughout 1943, as reported in E&MJ Metal and Mineral Markets, were given as follows (prices are per ton on an f. o. b. mill, Nevada, basis): Crude, in bulk, dried, $7, nominal; 98- to 100-mesh, $20; low-temperature insulation, $19; high-temperature insulation, $30. Diatomite for fine abrasives was quoted at 2 cents per pound. Bags are extra.

An illustrated description of the diatomite deposit near Lompoc, Calif., in production for half a century and now owned and operated by Johns-Manville Products Corporation, includes a history of the company's growth and development, its research activities, and the varied uses in which its products are employed, including many applications of direct and vital significance to the efficient prosecution of the war.[1] Diatomaceous earth, up to about 5 percent of the pulp, incorporated into white patent coated liner cardboard gave better formation, higher brightness and opacity of the liner, and increased operating efficiency.[2] In the deinking of old used fiber comprising a portion of the liner stock, the highly absorptive qualities of diatomaceous earth aided in a quicker and more thorough removal of the ink and produced a uniformly higher brightness in the final washed pulp. Substitution of diatomite for flint in different types of ceramic glazes results in a definitely improved gloss but an off-white color.[3] Small quantities of diatomaceous earth are produced in South Africa for use as a packing material.[4] A deposit of high-grade diatomite was discovered in Sweden.[5]

Tripoli.—Production of tripoli decreased 15 percent to 14,912 short tons valued at $244,365 in 1943, compared with 17,536 tons valued at $272,428 in 1942, and was only slightly above the 1932 figure. Output in 1943 was reported from Arkansas, Illinois, Missouri, Oklahoma, and Pennsylvania (rottenstone).

Tripoli (including Pennsylvania rottenstone) sold or used by producers in the United States, 1939–43

Year	Illinois		Other States [1]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1939	11, 134	$148, 310	22, 340	$318, 070	33, 474	$466, 380

Other uses [2]	2, 770	40, 428	2, 448	34, 465	1, 537	23, 498
	29, 301	421, 746	17, 536	272, 428	14, 912	244, 365

[1] Included under "Other uses."
[2] 1941: Foundry facing and unspecified; 1942: Foundry facing, drilling mud, and unspecified; 1943: Filter block, foundry facing, and unspecified.

Tripoli used for abrasive purposes in 1943 increased 13 percent, and that employed as a filler decreased 22 percent compared with 1942. Concrete admixture, foundry facing, and filter block were among the other uses specified. No tripoli was reported sold for oil-well drilling mud in 1943.

Quotations for tripoli in 1943 taken from E&MJ Metal and Mineral Markets were the same as those reported in 1942, as follows (prices are per ton, f. o. b. Missouri, in paper-lined burlap bags, minimum carload, 30 tons): Once ground through 40-mesh, rose or cream colored, $14.50; double-ground through 110-mesh, rose or cream, $16; air-floated through 200-mesh, $26.

Quartz.—Sales of crude, crushed, and ground quartz from pegmatite veins or dikes and from quartzite in 1943 advanced sharply compared with 1942, with only a moderate increase in total realization. Comparable data for 1943 and 1942, with percentages of increase over 1942 in parentheses, follow: 1943, 99,445 short tons (51 percent) valued at $346,558 (5 percent); 1942, 65,878 tons, valued at $331,494. The tonnage in 1943 was the largest reported since 1917 (142,673 tons), and the value, the highest since 1919 ($373,571). Sales of crude quartz in 1943 were approximately three times those in 1942, but ground quartz sold amounted to only slightly over half the volume reported in 1942. Crushed quartz, however, showed the largest absolute change, owing chiefly to its greater use in the manufacture of ferrosilicon.

Quartz (crude, crushed, and ground)[1] *sold or used by producers in the United States, 1939–43*

Year	Crude		Crushed		Ground		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

[1] To avoid duplication, the ground material shown here is only that ground by the original producers of the crude quartz or by grinders who purchase from small miners not reporting their production.

Eleven States produced quartz in 1943, compared with 15 in 1942. No output in 1943 was listed for New York, Ohio, Pennsylvania, and Texas.

Quartz (crude, crushed, and ground)[1] *sold or used by producers in the United States, 1941–43, by States*

[1] To avoid duplication, the ground material included is only that ground by the original producers of the crude quartz or by grinders who purchase from small miners not reporting their production

[2] Included under "Other States."

[3] 1941: Maryland, New Hampshire, New York, North Carolina, Tennessee, and Wisconsin; 1942: Arizona, California, Maryland, New York, North Carolina, Tennessee, Virginia, Washington, and Wisconsin; 1943: Arizona, California, New Jersey, Washington, and Wisconsin.

The chemical and physical properties of fused quartz were described in detail by Johnson.[6] Quartz from the Chestnut Flat mine of the Carolina China Clay Co., Penland, N. C., which was used in making the world's largest telescope, now is being purchased by a manufacturer of optical glass for use in high-quality lenses largely on military order.[7]

Ground sand and sandstone.—Sales of ground sand and sandstone in 1943 established new records in both quantity and value and totaled 541,350 short tons valued at $3,937,452, or 2 percent above 1917, the former record year in tonnage (532,454 tons), and 8 percent in value more than in 1942, the former peak year in total realization ($3,646,643). Tonnage marketed in 1943 was 3 percent greater than that reported for 1942. Output by States or groups of States for which comparisons are possible showed small gains in 1943 over 1942, except for New Jersey–Pennsylvania, where production (sales) decreased about 5 percent. States producing sizable tonnages of ground sand and sandstone are Illinois, New Jersey, Ohio, and Pennsylvania.

Distribution of sales, by uses, of ground sand and sandstone, as reported by 90 percent of the industry, reveals that the chief marketing outlets in 1943 were pottery, porcelain, and tile, foundries, and abrasives, in order of size of shipments. Manufacture of enamel and glass and users of various types of fillers consumed most of the remaining tonnage for which uses were reported.

[1] Data represent 90 percent of the industry.

Abrasive sands.—Considerable tonnages of natural sands with a high silica content are employed for abrasive purposes, such as sand blasting, stone polishing, glass grinding, or sandpaper. In 1943, sales of grinding and polishing sand totaled 837,662 short tons valued at $1,428,463, compared with 806,878 tons valued at $1,363,168 in 1942. Included in the 1943 total are 450,997 tons of blast sand valued at $1,138,003—7 percent more in tonnage and 6 percent higher in value than that reported for 1942.

SPECIAL SILICA-STONE PRODUCTS

Grindstones and pulpstones.—Total sales of pulpstones and grindstones in 1943 aggregated 12,623 short tons valued at $488,205, a decrease of 14 percent in tonnage and 10 percent in value compared with 1942, and were the lowest in both quantity and value since 1939. Marketed production of grindstones in 1943 was 16 percent under 1942 but was considerably in excess of the tonnages sold in 1938–40. Output of pulpstones in 1943 declined 1 percent in tonnage and about 18 percent in value compared with 1942. As in most recent years, pulpstones were produced in Washington and West Virginia and grindstones in Ohio and West Virginia.

Grindstones and pulpstones sold by producers in the United States, 1939–43

Year	Grindstones		Pulpstones		
			Quantity		Value
	Short tons	Value	Pieces	Equivalent short tons	
1939	7,917	$257,350	672	2,517	$169,025
1940	8,790	284,809	901	4,533	211,639
1941	13,573	434,208	685	1,963	111,348
1942	12,763	422,763	528	1,918	116,976
1943	10,732	392,296	323	1,891	95,909

Oilstones and related products.—Sales of natural sharpening stones, including oilstones, whetstones, scythestones, and rubbing stones, were slightly smaller in 1943 than in 1942. The Bureau of Mines, however, has not been at liberty to publish sales figures since 1939. States in which production was made in 1943 and the type of stone reported from each State were as follows: Arkansas—oilstones and whetstones; Indiana—scythestones, hones, and rubbing stones; New Hampshire—

scythestones; and Ohio—scythestones, whetstones, and "other" sharpening stones, including lathestones.

Millstones.—The value of millstones in 1943 declined 11 percent, to $9,240, compared with $10,391 in 1942. In 1943, millstones were produced in Ulster County, N. Y. ("Esopus" stone from the Shawangunk conglomerate); Rowan County, N. C. (granite); and Montgomery County, Va. (a fine-grained quartzite known as "Brush Mountain" stone). Output of chasers also was reported from New York. Early accounts of the production of millstones or burrstones in England, Germany, and France describe mining, preparation, and marketing in the first part of the 19th century.[8]

Value of millstones, chasers, and dragstones sold by producers in the United States, 1939–43

Year	New York		Other States [1]		Total

[1] 1939–40 and 1942–43: North Carolina and Virginia; 1941: North Carolina, Virginia, and West Virginia.
[2] Bureau of Mines not at liberty to publish figures.

Grinding pebbles and tube-mill liners.—Total sales of grinding pebbles and tube-mill liners in 1943 decreased 31 percent in both quantity and value compared with 1942. Sales of grinding pebbles were 36 percent under 1942. Tube-mill liners remained at virtually the same level as in 1942, although the average realization was somewhat lower. The Bureau of Mines was not able to publish totals for grinding pebbles and tube-mill liners from 1933 to 1941.

Grinding pebbles were produced in 5 States in 1943—California, Minnesota, North Carolina, Texas, and Wisconsin—and tube-mill liners were reported from 3 States—Minnesota, North Carolina, and Wisconsin. No production of pebbles from Elmore, Ala., was reported, as the Great Lakes Foundry Sand Co., Detroit, Mich., has discontinued operations there. Beach pebbles were gathered and sold by John T. Momand, Carlsbad, Calif.

Grinding pebbles and tube-mill liners sold or used by producers in the United States, 1941–43

Year	Grinding pebbles		Tube-mill liners		Total	
	Short tons	Value	Short tons	Value	Short tons	Value

[8] The Stone Trades Journal, Ancient Mill-Stone Quarries: Vol. 66, No. 6, June 1943, pp. 79–80.

Granite Quarries Co., Salisbury, N. C. Peeler & McCombs, Faith, N. C., also sold some granite cubes and liners produced in the same region.

Philip S. Hoyt, Van Horn, Tex., shipped flint pebbles from various locations, principally Bastrop and Colorado Counties, Texas. Both the Arlcy Mining Co., Pearsall, Tex., and Dezendorf Marble Co., Austin, Tex., shipped flint pebbles in 1943, although the Arlcy Mining Co. was reported to have discontinued operations in the spring of the year.

Quartzite pebbles and liners from Sauk County, Wis., were marketed by the Baraboo Quartzite Co., Baraboo, Wis. A detailed description of the quarry operations and the mill of this firm was published in the trade press.[9] In addition to its quartzite products, mill liners are produced from waste monumental granite, which is cut to size and tapered. A brief history of the mining and processing of grinding pebbles in the coastal plain of Texas and a detailed account of the occurrences in this region were given by Parkinson and Barnes.[10]

NATURAL SILICATE ABRASIVES

Pumice and pumicite.—The curtailment of private building operations due to wartime restrictions was chiefly responsible for the 33 percent decline in tonnage of pumice and pumicite sold in 1943. The value of sales decreased 13 percent. Sales in 1943, however, were larger than in any year previous to 1939.

As in 1942, pumice or pumicite was produced in 7 States. Output from Washington was reported in 1943, although no production was listed from Oregon. The shifts in relative rank of the States from 1942 to 1943, as shown in the accompanying table, as well as the tonnage changes, may be ascribed to the lack of active construction and the increased demand for abrasives and cleansing preparations.

Pumice and pumicite sold or used by producers in the United States, 1939–43

Year	Short tons	Value	Year	Short tons	Value
1939	89,159	$424,780	1942	126,522	$706,199
1940	82,407	449,914	1943	85,150	611,495

[10] Parkinson, George A., and Barnes, Virgil E., Grinding Pebble Deposits of Western Gulf Coastal Plain of Texas: Separate from The University of Texas Publication 4301, March 1944, pp. 47–54.

The use of pumice and pumicite for abrasive purposes expanded 17 percent in 1943, compared with 1942, and accounted for about 75 percent of total sales. (See fig. 1.) Consumption in building industries dropped decisively and reflected the drastic restrictions on private construction due to war regulations. Tonnage of pumice or pumicite used in acoustic plaster was 64 percent less in 1943 than in 1942, and the quantity consumed in the manufacture of concrete aggregate and concrete admixture decreased 70 percent. In addition to those uses for which tonnages are shown, other sales outlets included insecticides, brick manufacture, filtration, and paint filler.

A description of the pumice recovery and processing procedure of operations of the Pumice Corporation of America, near Grants, N.

Mex., was published.[11] Recent improvements in grinding and refining have resulted in a pumice at least equivalent and in some respects superior to the Italian material formerly imported from Lipari Islands, according to the author. The long overland haul from New Mexico or California, however, is a distinct disadvantage with respect to costs, compared with the delivered value of the Italian product in eastern United States markets. Pumice is produced regularly in New Zealand,[12] and the volcanic dust and lava from Mexico's Paricutin volcano has been made into ceramic ware.[13]

Garnet.—Abrasive garnet sold in 1943 totaled 5,935 short tons valued at $429,120, or 36 percent higher in quantity and 43 percent in value than in 1942. These figures were the highest reported to the Bureau of Mines since 1929. (See fig. 2.) Garnet was produced in 1943 in Idaho, New York, and North Carolina. Quotations on garnet, as reported by E&MJ Metal and Mineral Markets, were unchanged during 1943: New York Adirondack garnet concentrates, grain, were listed at $85 per ton, and Spanish grades, c. i. f. port of entry, were nominally quoted at $70 per ton.

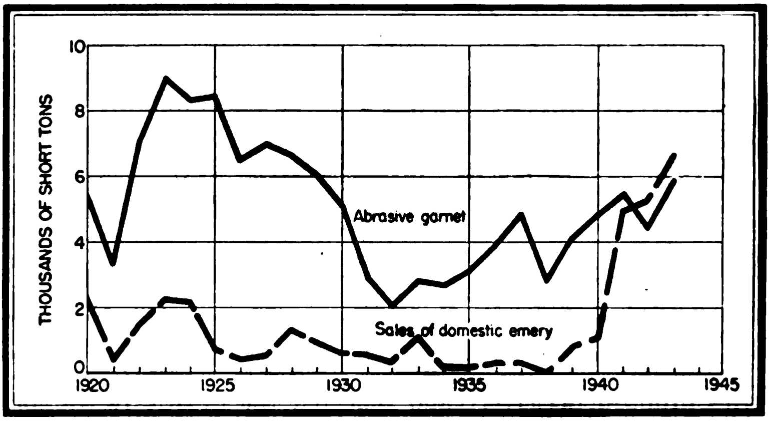

FIGURE 2.—Marketed production of abrasive garnet and domestic emery in the United States, 1920–43.

Abrasive garnet sold or used by producers in the United States, 1939–43

Year	Short tons	Value	Year	Short tons	Value
1939	4,056	$278,534	1942	4,357	$299,904
1940	4,716	259,345	1943	5,935	429,120
1941	5,501	371,752			

The first nonmetallic plant to adopt heavy-media separation (float-sink) processes and the first plant to use ferrosilicon as the separating medium other than in iron-ore treatment is the garnet-concentrating mill of the Barton Mines Corporation, North Creek, N. Y. Increased garnet production with existing equipment and at no additional labor cost and a greater proportion of garnet recovery in the minus ½-inch plus ⅛-inch range are among the advantages claimed by the operators.

[11] Kutnewsky, Fremont, Pumice—Nature's Unique Abrasive: Compressed Air Mag., vol. 48, No. 6, June 1943, pp. 7063-7065.
[12] South African Mining and Engineering Journal, vol. 53, pt. 2, No. 2613, February 27, 1943, p. 572.
[13] Science News Letter, November 13, 1943, p. 312.

A detailed description of the mill (including a flow sheet) and its operation was published by Vogel.[14] A new fire-resistant nonskid deck covering especially adapted for use around gun emplacements on battleships has been perfected and is now in use by the Navy. The abrasive element consists chiefly of garnet or aluminum oxide particles held in a special plastic synthetic-resin binder. It is stored as a viscous fluid in metal containers, ready for use, and may be applied with a trowel or by spray guns to wood, concrete, or steel. Drying in a few hours, the coating is durable, unaffected by ordinary temperatures, and corrosion-resistant.[15] Of interest is the development of finely ground garnet as an abrasive for grinding vitally needed opthalmic and precision lenses in the optical industry. Actual production tests of properly classified garnet flours have produced finishes comparable to those obtained by the use of corundum or synthetic abrasive superfines, according to the War Production Board, but required 20 percent longer grinding time.

NATURAL ALUMINA ABRASIVES

Corundum.—Corundum, a natural alumina abrasive, is especially adapted for use in the manufacture of grinding wheels employed in essential industry and as a polishing agent for precision lenses. The coarser grain sizes are purchased by the grinding-wheel manufacturers and the finer-sized products by optical-lens makers. The fine dust remaining after use by the optical instrument grinders is sold to retail opticians.

Until 1943, no production of natural corundum had been reported in the United States since 1917 and 1918, and none previous to those years since 1906. By far, most of the corundum used in this country in recent years has been imported from the Union of South Africa, and small amounts in various years from several other countries. Because of the dangers incident to the long ocean haul from Africa, the shortage of shipping space, and the comparative scarcity of corundum reserves, intensive search for possible domestic commercial deposits was undertaken. Examination of known occurrences and revaluation of old abandoned properties were especially active in Montana, North Carolina, and South Carolina.

Mining operations were begun during 1943 in South Carolina by Withers, Inc., at a formerly active property near Clover. This deposit comprises three veins of corundum and contains material said to approximate closely in quality that received from Africa. Tests by the optical industry are understood to have been favorable.[16]

Emery.—Sales of domestic emery in 1943 increased 26 percent in tonnage and 28 percent in value, compared with 1942 (see fig. 2), and were the highest recorded since 1918. As in former years, the entire output was produced in the Peekskill (N. Y.) area. In addition to its augmented use in abrasive products, emery also is in demand as a nonslip, wear-resistant ingredient in concrete floors. According to E&MJ Metal and Mineral Markets, crude domestic emery ore was quoted in 1943 at $10 per ton for first-grade material f. o. b.

1941	4,876	42,484			

NATURAL CARBON ABRASIVES [18]

Abrasive or industrial diamonds.—Estimates, considered reliable, have placed the value of total sales of industrial diamonds in 1943 at £6,000,000, compared with £4,250,000 in 1942 and £2,000,000 in 1941.[19] This large increase in sales of industrial stones is the result not only of the vast wartime manufacture of ships, planes, and munitions, but also of the more widely diversified use and applications of diamond-set tools for drilling, grinding, and wheel-dressing operations and the greatly increased need for wire-drawing dies, especially in radio equipment.[20] Another indication of the more extensive use of abrasive diamonds is the relative total weight of diamonds used for gems and for industrial purposes. Before the war, about 30 percent by weight was estimated as industrial diamonds. At present this percentage is variously estimated at 70 to 80 percent. The demand for industrials has become so strong that much of the smaller flawless stone normally marketed as gem material is being diverted to abrasive purposes or to be used as dies. Improved methods of crushing and sieving also have resulted in much finer and more uniform sizes of diamond dust, even down to 1 micron in diameter. Diamond dust in these finer sizes now is vitally important in polishing operations in war industries, particularly in the manufacture of precision lenses and in imparting supersmooth finish to bearings.[21]

A good account of the role of diamonds and natural and artificial sapphires and rubies in present-day industry was published.[22] A comprehensive summary of the diamond industry was published in 1943.[23] The extremely active market for both gems and industrial stones was discussed by countries of output and by markets where sold. An appraisal of the position of the Allied Nations and the Axis countries was made with respect to the relative abundance or scarcity of supplies currently available for use in war production. The use of diamonds in blast-hole mining and pillar recovery is increasing and consumption for diamond-set tools and diamond dies is greater than heretofore. Likewise, the use of crushing bort in bonded wheels and other tools and diamond dust for grinding vital parts of radio and radar equipment has increased greatly.

ARTIFICIAL ABRASIVES

The expanded industrial output, particularly of munitions, ships, planes, and other war matériel, resulted in substantial increases in the production and sales of aluminum oxide, silicon carbide, and metallic abrasives. Both the combined total output of manufactured abrasives and each class individually established records in 1943 for the third successive year. Although the capacity of plants to produce was substantially increased during the year, operation, as in other recent years, continued at virtually the maximum possible for both silicon carbide and aluminum oxide (98 percent of capacity). Production of silicon carbide in 1943 was 13 percent higher and of aluminum oxide 18 percent higher than in 1942. Operating at about 73 percent of capacity, manufacturers of metallic abrasives (steel shot and grit) increased their shipments 17 percent in 1943 compared with 1942.

Crude artificial abrasives sold, shipped, or used, from manufacturing plants in the United States and Canada, 1939–43

[1] Production; Bureau of Mines not at liberty to publish data for United States separately. Figures include material used for refractories and other nonabrasive purposes.

[2] Figures include only shipments from United States plants.

[3] Revised figures.

Production of silicon carbide and aluminum oxide is concentrated largely in the Niagara Falls region of Canada and the United States; some aluminum oxide, however, is produced in Quebec (Canada) and in Alabama. The same companies that produced aluminum oxide and silicon carbide in 1942 and other recent years were active in 1943. Included in the total for aluminum oxide in 1943 is 28,127 tons of the type designated as "white high purity or special," valued at $3,191,768. Increased consumption of silicon carbide in refractories is reflected in the estimated 41 percent of total production used for nonabrasive or refractory purposes in 1943, compared with 35 percent in 1942, 32 percent in 1941 and 1940, and 29 percent in 1939. Similar data for aluminum oxide indicate much lower percentages of total output employed for nonabrasive or refractory purposes—4 percent in 1943, 3 percent in 1942 and 1941, 2 percent in 1940, and 4 percent in 1939.

Statistics for metallic abrasives cover steel shot and grit (including figures for one firm that manufactures a similar product from salvaged wire clippings) but not steel wool. In 1943, metallic abrasives were manufactured in Massachusetts, Michigan, New Hampshire, Ohio (the chief producing State), and Pennsylvania. Twelve companies with 13 plants reported shipments in 1943, compared with 8 companies and 9 plants in 1942. Two new plants, one in Illinois and one in New York, were scheduled to begin operations early in 1944.

On the occasion of his acceptance of the Jacob F. Schoellkopf medal, Ridgway traced the development of the manufacture of aluminous artificial abrasives.[24] He particularly stressed the physico-chemical reactions in electric-furnace production of fused aluminum oxide and described the methods of manufacture of grain and molded forms of boron carbide and the industrial applications for which they are especially suited. Modern methods of using abrasive grains, particularly aluminum oxide and silicon carbide, were described by Heywood,[25] who presents a good practical discussion of polishing, flexible grinding and buffing methods, lapping with abrasive grain, use of grain in the glass and optical industries, and various miscellaneous uses. Suggested grain sizes of various types of abrasives applicable to specific grinding, polishing, and lapping operations based on actual experience are given in the text and in tabular form. The manufacture and grading of abrasives and standardization of sieve sizes were discussed by Walton.[26] Methods were described for reclaiming abrasive grain from polishing refuse,[27] and for separating an impure crystalline alumina from its adhering slag to recover abrasive crystal values.[28]

MISCELLANEOUS MINERAL ABRASIVE MATERIALS

In addition to the natural and manufactured abrasive materials herein discussed, many other mineral substances are used for abrasive purposes. Various oxides, including tin oxide, rouge, crocus, chromium oxide, magnesium oxide, and manganese oxide, are utilized as polishing agents. Among manufactured or artificially prepared products used or intended for use as abrasives are boron carbide, a periclase abrasive made from magnesite, a product made by fusing quartz with a mixture of magnesia and magnesium chloride (reported from Costa Rica),[29] and an abrasive consisting of a mixture of powdered metal and crushed diamond bort (developed by South African scientists).[30] Finely ground as well as calcined clays, high-grade lime, talc, river silt, slate flour, whiting, feldspar, and other substances also are used as abrasives.

FOREIGN TRADE [31]

Stimulated by the need for grinding wheels for tool steels and polishing media for lenses and other precision instruments, imports of corundum in 1943 increased 20 percent in tonnage and 28 percent in value over 1942 and were only 3 percent under the high year, 1941. Imports of ground, pulverized, or refined corundum and emery grain, however, nearly doubled in 1943 compared with 1942. (Although not shown separately, the bulk of this item probably is corundum grain.) No imports of emery ore were reported in 1943. Receipts of crude pumice remained at a low level, and no pumice "manufactures" were listed. Imports of tripoli and rottenstone were insignificant. "Flint, flints and flint stones, unground" imports in 1943 were somewhat higher than in 1942 but were still considerably under those of other recent years. Imports of industrial diamonds, comprised largely in the classification "glaziers', and engravers', unset, and miners' diamonds," rose 8 percent above the exceptionally large receipts of 1942, although the average value per carat declined. This lower value reflects the current trend toward the use of smaller diamonds in impregnated or bonded cutting and grinding tools and for other purposes. A very large increase in imports of diamond dust was indicated in 1943.

[31] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the United States Department of Commerce.

The total value of exports of natural abrasive materials in 1943 declined 47 percent compared with 1942 but was 10 percent above 1941. Each class of exports of abrasive shown in the accompanying table had a value less than in 1942—grindstones, only 5 percent; emery and corundum abrasive wheels, 64 percent; and all other natural abrasives and abrasive products, 28 percent.

GENERAL SUMMARY

For widely varying reasons, world production of native sulfur decreased sharply in 1943. During the year Sicily was at the edge or at the center of a battle zone—a condition that reduced sulfur production to negligible proportions. In the United States past years of record-breaking output had accumulated such stock piles that in spite of an increase in consumption operators were able to throttle back production to a rate that would gradually reduce these stocks.

As the submarine menace was brought under control more bottoms were assigned to the transportation of sulfur. Consequently exports increased, relieving shortages in various Allied and neutral countries. This development tended to ease the search for domestic sources in many, but not all, importing countries. Notable exceptions are Argentina, which is turning to its native sulfur deposits, and Great Britain, which continued its investigation of coal byproducts.

The status of pyrites production in 1943 is clouded by lack of authentic information from Axis-dominated areas. Output in Spain, Portugal, and Cyprus is curtailed in varying degree by shipping restrictions. Rumors indicate that Germany is suffering an acid shortage, but it is not clear that the cause is deficiency in raw materials. Although many countries that formerly purchased pyrites from Spain and other exporters have succeeded in finding alternative sources, total world production in 1943 probably was somewhat below a record level.

In the United States prices of sulfur and acids were comparatively stable, and with minor exceptions, the Office of Price Administration continued the General Maximum Price Regulation. Such an ample supply of sulfur was available that the War Production Board found allocation unnecessary. However, more difficulty was encountered in supplying the demand for sulfuric acid, and it was placed under allocation in the last part of the year.

---

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the United States Department of Commerce.

POST-WAR OUTLOOK

Satisfactory progress in the war has focused attention on post-war problems. Some concern is evident among the acid producers because of the substantial increase in sulfuric acid production capacity since 1939. Undoubtedly, some obsolete and some war-born acid plants will be unable to find profitable peacetime markets in their shipping areas, and competition may be very active, even in the best markets. Recovery of byproduct sulfur compounds from oil refining and acid sludges gradually may make the petroleum industry more self-sufficient; on the other hand, some believe that future production methods may require the purchase of even greater quantities of sulfur. Competitive materials having particularly advantageous properties occasionally threaten to usurp important markets—for example, hydrofluoric acid in oil refining—but even here sulfuric acid appears capable of defending its position.

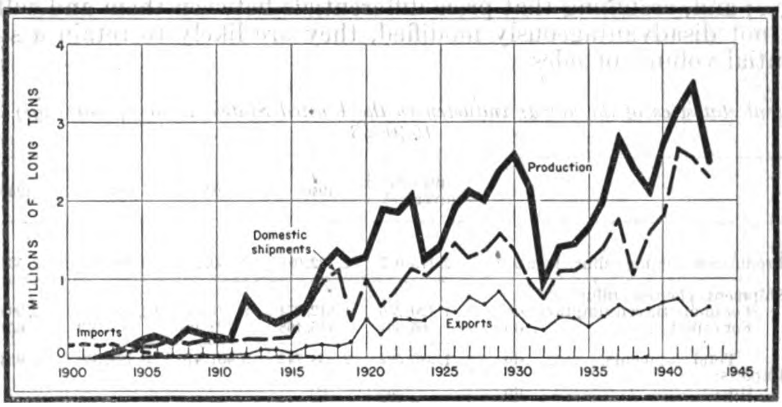

FIGURE 1.—Domestic production, shipments for domestic consumption, exports, and imports of crude sulfur, 1900–1943.

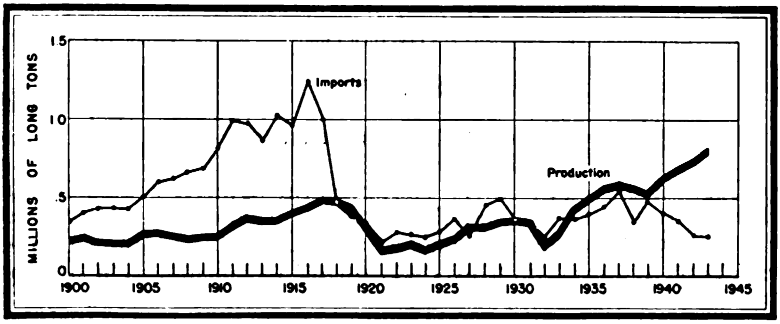

FIGURE 2.—Domestic production and imports of pyrites, 1900–1943.

Fortunately the industry has a very solid foundation in the fact that sulfuric acid costs substantially less than the next cheapest mineral acid. As in past years, the technical literature indicates that new products and methods are enlarging rather than limiting the sulfur market. As the curve of acid consumption closely approximates that of business activity, the market will be determined largely by the degree of general prosperity attained.

In any case, the position of the domestic native sulfur industry appears to be assured. During the past few years the United States has come to depend more and more completely on native sulfur rather than on imported or even domestic pyrites. On the other hand, domestic and imported pyrites have local competitive advantages; and, assuming that price differentials between them and sulfur are not disadvantageously modified, they are likely to retain a substantial volume of sales.

Salient statistics of the sulfur industry in the United States, 1935–39 (average) and 1940–43

	1935–39 (average)	1940	1941	1942	1943

SULFUR

DOMESTIC PRODUCTION

Production of crude native sulfur in the United States in 1943, conducted at a rate calculated to reduce producers' stocks, was 27 percent below the record tonnage attained in 1942. Mine shipments were 6 percent lower than in 1942, owing to consumption of stocks accumulated in previous years at other locations. In addition to the tonnage of relatively pure crude sulfur reported as the United States total, a comparatively small amount of native sulfur-bearing ore, containing 10 to 50 percent sulfur, was mined in Texas (3,500 long tons) and Colorado and sold for agricultural purposes.

REVIEW BY STATES

Texas contributed 75 percent and Louisiana 25 percent of the native sulfur mined in the United States in 1943. California and Utah reported no production.

Sulfur produced and shipped in the United States, 1939–43

Year	Produced (long tons)				Shipped	
	Texas	Louisiana	Other States [1]	Total	Long tons	Approximate value
1939	1,665,400	422,600	2,979	2,090,979	2,233,817	$35,500,000
1940	2,212,839	512,935	6,314	2,732,088	2,558,742	40,900,000
1941	2,596,731	533,620	8,902	3,139,253	3,401,410	54,400,000
1942	2,885,621	570,345	4,720	3,460,686	3,128,559	50,100,000
1943	1,908,581	630,205	....	2,538,786	2,953,845	47,300,000

[1] 1939–40 and 1942: California and Utah; 1941: California.

Colorado.—Thomas Sulphur Co. mined sulfur ore in Delta County.

Louisiana.—Output from the Grande Ecaille mine of the Freeport Sulphur Co., Plaquemines Parish, increased to 630,205 long tons in 1943.

Texas.—The following companies operated in Texas in 1943: Duval Texas Sulphur Co., at Orchard Dome, Fort Bend County; Freeport Sulphur Co., at Hoskins Mound, Brazoria County; Jefferson Lake Sulphur Co., Inc., at Clemens Dome, Brazoria County; Texas Gulf Sulphur Co., at Boling Dome, Wharton County; and the Pecos Orla Sulphur Co. mined sulfur ore at the Michigan claims in Culberson County. It is reported that the Jefferson Lake Sulphur Co. is preparing to start production from a dome in Fort Bend County when Clemens Dome is exhausted.

The following table was compiled from information issued by the Texas State Comptroller's Office.

Sulfur produced in Texas in 1943, by companies, in long tons

Company	First quarter	Second quarter	Third quarter	Fourth quarter	Total
Texas Gulf Sulphur Co	321,838	311,958	260,812	292,274	1,186,882
Freeport Sulphur Co	107,730	97,125	96,180	96,590	397,625
Jefferson Lake Sulphur Co., Inc	44,178	38,508	30,705	35,903	149,294
Duval Texas Sulphur Co	51,360	44,085	38,355	40,980	174,780
	525,106	491,676	426,052	465,747	1,908,581

RECOVERY AS BYPRODUCT

The total sulfur available in byproducts of industrial processes is very large; but most of this material is discarded, as only a fraction can be profitably recovered at present.

Copper and zinc ores and coal-mine wastes commonly contain large quantities of pyrites, and substantial tonnages are now concentrated and used in the manufacture of sulfuric acid. Such output is recorded in the Pyrites section of this chapter.

During smelting, concentrates of copper and zinc sulfides themselves give off sulfur dioxide and other sulfur-bearing gases, which are converted to sulfuric acid at many smelters. The equivalent of about 210,000 long tons of sulfur was recovered annually from this source during the five years ended in 1943. The following table shows the output of acid at copper-, lead-, and zinc-smelting plants.

Byproduct sulfuric acid [1] *(expressed as 60° B.) produced at copper and zinc plants in the United States, 1939–43, in short tons*

	1939	1940	1941	1942	1943
Copper plants [1]	249, 569	254, 025	243, 812	265, 522	348, 832
Zinc plants	528, 872	586, 912	672, 177	695, 242	846, 875
	778, 441	840, 937	915, 989	960, 764	1, 195, 707

[1] Includes sulfuric acid produced as byproduct at a lead smelter.

In addition to serving as a means of producing a profitable byproduct, recovery of sulfur or its compounds from coke-oven, refinery-still, natural, or other gases also provides more intangible benefits. Sulfurous gas is destructive to equipment and vegetation, and its removal often reduces plant-maintenance costs and eliminates a nuisance in the surrounding area. In 1943 the Ford Motor Co. installed a Thylox-process plant to produce sulfur from coke-oven gas.

Most of the elemental sulfur derived from gas purification comes from plants using the Thylox process; relatively small quantities are removed with the Ferrox and Nickel processes. Production in 1943 (in terms of 100 percent sulfur) total 5,101 long tons; 4,735 tons valued at $190,755 were shipped. Output came from Illinois, Maryland, Massachusetts, Michigan, Missouri, New Jersey, New York, Washington, West Virginia, and Wisconsin; Massachusetts and New York were the largest producing States. Of the 1943 shipments (calculated as 100 percent sulfur), 41 percent was marketed in the form of paste containing 38 to 52 percent sulfur, and 59 percent was sold in dried relatively pure condition.

Fuel gases also yield hydrogen sulfide through the phenolate, phosphate, and Girbotol processes. In 1943 the hydrogen sulfide recovered contained 17,591 long tons of sulfur and came from plants in California, New Jersey, and Pennsylvania. Most of this material subsequently was converted into sulfuric acid.

The figures covering the byproduct yield of sulfur from gas purification are not included in the sulfur-production figures for the United States.

STOCKS

During 1943 the total of producer-owned stocks declined 13 percent to 4,462,000 long tons. At the end of the year 3,841,000 long tons were held at the mines and the remainder at consumption centers or in transit.

PRICES

Throughout 1943 crude sulfur was quoted by trade journals at $16 per long ton f. o. b. mines and sulfuric acid, 66° B., at $16.50 per short ton at works in tank cars. The Office of Price Administration contemplated issuing a fixed schedule of prices for sulfuric acid; but, after a detailed study revealed a stable price situation, action was withheld. An independent investigation by the Bureau of Labor Statistics, United States Department of Labor, showed that average acid prices were the same in 1943 as in 1939. As many of their costs have risen, some acid producers found themselves in an unfavorable position. Limited relief was granted such manufacturers on certain long-term contract sales.

Although demand was at record levels, information from the industry indicates that the trend of sulfur prices is down.

CONSUMPTION AND USES

Consumption of sulfur in the United States attained a new record in 1943. The 2-percent increase indicated in the following table, showing apparent domestic consumption during the past 5 years, may be slightly low, as it does not allow for the comparatively small tonnage believed to have been withdrawn by consumers from stock piles they have accumulated in previous years.

Apparent consumption of sulfur in the United States, 1939–43, in long tons

	1939	1940	1941	1942	1943
Shipments [1]	2,233,817	2,558,742	3,076,038	3,032,043	3,191,051
Imports	13,976	27,845	28,631	25,632	16,658
	2,247,793	2,586,587	3,104,669	3,057,675	3,207,709
Exports:					
Crude	627,819	746,468	729,464	568,249	654,393
Refined	25,005	19,745	31,312	17,030	28,079
	652,824	766,213	760,776	585,279	682,472
Apparent consumption	1,594,969	1,820,374	2,343,893	[2] 2,472,396	2,525,237

[1] 1939–40: Mine shipments; 1941–43: Apparent shipments to consumers.
[2] Revised figure.

The pattern of industrial sulfur consumption has been estimated by Chemical and Metallurgical Engineering as follows:

Sulfur consumed in the United States, 1939–43, by uses, in long tons

Use	1939	1940	1941	1942	1943
Chemicals	695,000	800,000	[1] 1,060,000	[1] 1,260,000	[1] 1,320,000
Fertilizer and insecticides	370,000	410,000	450,000	475,000	500,000
Pulp and paper	240,000	320,000	360,000	365,000	305,000
Explosives	64,000	74,000	[1] 83,000	[1] 90,000	[1] 90,000
Dyes and coal-tar products	46,000	51,000	65,000	60,000	65,000
Rubber	43,000	47,000	55,000	35,000	45,000
Paint and varnish	49,000	54,000	65,000	70,000	80,000
Food products	6,000	6,000	6,000	6,000	7,000
Miscellaneous	82,000	86,000	95,000	110,000	120,000
	1,595,000	1,848,000	2,239,000	2,471,000	2,532,000

[1] To avoid disclosing estimated consumption of sulfur in direct defense applications, such as military explosives, sulfur so used in 1941–43 is included under "Chemicals."

Over three-fourths of the sulfur, from all sources, consumed in the United States is converted into sulfuric acid before entering its final use. Production of sulfuric acid is estimated to have expanded from 12,520,000 short tons (calculated as 50° B.) in 1942 to 13,930,000 short tons in 1943, or 11 percent.[2]

Chemical and Metallurgical Engineering has estimated the consumption of sulfuric acid, by industries, from 1939 through 1943 as follows:

Sulfuric acid (expressed as 50° B.) consumed in the United States, 1939–43, by industries, in short tons

Industry	1939	1940	1941	1942	1943
Fertilizer	1,970.000	2,260,000	2,500,000	2.950.000	4,100,000
Petroleum refining	1,210,000	1,260.000	1.400,000	1.650,000	1.720.000
Chemicals	975,000	1.120.000	[1] 1.790,000	[1] 2,250,000	[1] 2.350.000
Coal products	740,000	900.000	940,000	970,000	927,000
Iron and steel	980.000	1.300.000	1.500,000	1,600.000	1,650,000
Other metallurgical	570.000	640,000	800,000	840,000	860.000
Paints and pigments	520,000	580,000	700,000	760,000	800,000
Explosives	160,000	170.000	[1] 190,000	[1] 195.000	[1] 190,000
Rayon and cellulose film	405,000	470.000	555.000	625.000	635.000
Textiles	116.000	125.000	165,000	145,000	135,000
Miscellaneous	384,000	360,000	500.000	530.000	550,000
	8,030,000	9,185,000	11,040,000	12,515,000	13,917,000

[1] To avoid disclosing estimated consumption of acid in direct defense applications, such as military explosives, acid so used in 1941-43 is included under "Chemicals."

Whereas most industries made modest increases and a few equally modest decreases, the big expansion in demand was found in the fertilizer industry, which used 39 percent more sulfuric acid than the record attained in 1942. Wartime food requirements and high farm income combined to drive superphosphate sales to unprecedented heights. Nor was the end in sight. At the year end, seven new fertilizer plants were scheduled for construction during 1944. The over-all 11-percent increase in acid consumption was not beyond the capabilities of installed plant capacity; but some areas, particularly in the West, were inadequately supplied owing in part to transportation difficulties. Shipments of fertilizer-grade acid from ordnance plants were also smaller than expected. Construction of additional plants in the shortage areas was contemplated.[3]

FOREIGN TRADE

In 1943 the shipping situation improved, allowing the export of 15 percent more crude and 65 percent more treated sulfur than in 1942. The following table shows the distribution, by countries, of our wartime sulfur exports.

The comparatively minor quantity of elemental sulfur imported into the United States comes principally from Canada. Canada also supplied 32,315 short tons of sulfuric acid, whereas exports from the United States totaled only 4,558 short tons.

[1] Less than 1 ton.

WORLD PRODUCTION

Although few official statistics are available, it is apparent that total world production of elemental sulfur declined sharply in 1943 and, even including that derived from gases, probably did not exceed 3,200,000 long tons. For widely different reasons the two main producing countries—the United States and Italy—failed to maintain the pace set in 1942.

World production of native sulfur, 1937–43, by countries, in long tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1937	1938	1939	1940	1941	1942	1943

[1] Native sulfur believed to be produced also in China, Cuba, India, Iran, Taiwan, and U. S. S. R., but quantity unknown.

[2] In addition, 1,050 tons of sulfur rock (40–80 percent sulfur) reported for 1937.

[3] Data not available.

[4] In addition, following quantities of sulfur rock reported—1937: 19,793 tons; 1938: 16,545 tons. Similar data not available for later years.

[5] Exports.

[6] Estimated sulfur content of ore, excluding sulfur made from pyrites.

Argentina.—Argentina has taken measures intended to make the country self-sufficient in sulfur in the relatively near future. In August 1943 the Government formed a mixed corporation with Compañía Azufrera Argentina S. A., principal Argentine sulfur producer. The new corporation, Industrias Quimicas Nacionales, S. M., receives a third of its financial backing, exclusive prospecting rights, and assistance in marketing from the Government. Present annual consumption of sulfur in Argentina is said to be about 30,000 tons, and the expectation is that the present refining capacity of 12,000 tons a year is to be enlarged sufficiently to supply the entire domestic market. Prices are now about 350 pesos a ton, but the new company has contracted to deliver at 250 pesos, and it is hoped that Argentine sulfur can be sold for 150 pesos after the refining plant has been expanded, production methods improved, and transportation cost reduced. The pre-war price of imported sulfur was 130 pesos per ton.

The sulfur deposits are in the Provinces of Mendoza and Salta (formerly in the Territory of Los Andes) near the Chilean border. At present production is coming from a single mine, the Cerro Estrella, about 100 kilometers south of Socompa. Mine-run material is carried by trucks 10 miles to the refinery, and the refined sulfur 80 miles to railhead. The deposit is said to contain 8 million tons of ore averaging 60 percent sulfur.

Chile.—In 1943 the Chilean sulfur industry enjoyed a great advantage in the South American market, as competition was restricted by war conditions. Demand was active, and it was reported that prices advanced from $50 to $75 and even to $100 per ton. Apparently consumers considered prices to be excessive, and demand was reduced to a point that caused considerable concern. An association was formed through which producers could cooperate in solving common problems. It is widely believed that Chilean producers must improve their processes and reduce prices to continue in business on a substantial and permanent basis. Reduction of the high cost of transportation will be difficult, though not impossible. The purity of the Chilean product, which has always suffered by comparison with the American, may be improved by a method, now being tried on a pilot-plant scale, by which impurities are agglomerated by treatment with sulfuric acid and subsequently filtered or settled out. At present Chile consumes only 6,000 to 8,000 tons of sulfur a year, so the industry must look for most of its volume in the foreign market. More than 220 sulfur properties have been listed. The three principal producers are: Compañía Azufrera del Pacifico, Tacora; Compañía Azufrera Alcanquilcha, Ollague; and Luis Borlando, Buenaventura, Ollague.[4]

Mexico.—Sulfur has been produced in Mexico for several hundred years, but the industry has never achieved major stature. The greatest annual output on record is 9,600 tons, obtained in 1912 from deposits in the State of San Luis Potosí. At present approximately 300 to 400 tons of crude sulfur are produced monthly, largely from the vicinity of Mexicali in northern Lower California. Occurrences of sulfur have been reported from at least 18 States of the Republic, but most of them are too small to support large-scale operations.[5]

Sicily.—Evidence accumulates that this war has fallen far short of benefiting Sicily's sulfur industry. The following production statistics, in long tons, tell a story of steady decline: 1939, 211,328; 1940, 198,192; 1941, 150,368; and 1942, 93,980. The number of mines dropped from about 100 in 1939 to 74 in 1942, and prices advanced from 584 lire in 1940 to 800 lire in 1942 and finally to 1,500 lire just before the invasion. Output in 1943 apparently was negligible. During the first 6 months of 1943 Sicily served principally as a base for Axis armies. Lack of electricity, shipping space, and necessary supplies made sulfur production nearly impossible, and when the invasion struck early in July operations ceased.

---

[4] Mineral Trade Notes, Confidential Series 20, February 1944, pp. 39-45.

[5] See footnote 4.

Sicilian sulfur can be used to advantage in certain Mediterranean, European, and even Asiatic areas. Late in the year Allied authorities initiated a program intended to reactivate the industry. A price of 1,700 lire was established, and efforts were made to obtain supplies and power. The island is still in an exposed position in the war zone, but it is hoped that a minimum of 50,000 long tons of sulfur will be produced in the fiscal year 1943–44.[6]

Spain.—At present Spain is self-sufficient in elemental sulfur. Native sulfur produced by Industrial Quimica de Zaragoza, Coto Minero de Hellin, and Romero Hermanos de Almeria totals about 5,000 tons annually. The bulk of the elemental sulfur is supplied by the Rio Tinto Co. of Huelva, which has reached a yearly output of 27,000 tons derived from pyrites processed by the Orkla method. Spain's annual consumption requirements are estimated to be slightly over 30,000 tons, but with expansion of the rayon industry they are expected to increase to 55,000 tons.[7]

Turkey.—Production in Turkey is limited to about 4,000 tons of highly bituminous sulfur from the Keciburlu mine, and most of this material is unsuitable for refining. Turkey's sulfur requirements are estimated to be about 6,000 tons annually.

PYRITES

DOMESTIC PRODUCTION

As in the 3 previous years, production of pyrites in the United States attained a new record in 1943, exceeding the 1942 total by 11 percent. Nearly all (96 percent) of the domestic pyrites output in 1943 was classified as fines and the remainder as lump.

Pyrites (ores and concentrates) produced in the United States, 1939–43

Year	Quantity: Gross weight (long tons)	Quantity: Sulfur content (percent)	Value
1939	519,497	42.3	$1,560,000
1940	626,640	41.8	1,920,000
1941	645,257	41.9	2,009,000
1942	720,363	42.6	$2,464,000
1943	802,384	40.9	2,844,000

Most domestic pyrites are consumed by the producing companies. Whereas in 1942 the producers sold 234,639 long tons and converted 492,720 into other products, in 1943 they marketed 202,774 tons and consumed 591,779.

REVIEW BY STATES

California.—Virtually all the pyrites recovered in California in 1943 came from the Hornet mine of the Mountain Copper Co., Shasta County.

Colorado.—Five organizations contributed to the 15,215-ton Colorado total in 1943: Minnesota Mines, Inc., Clear Creek County; Rico Argentine Mining Co., Dolores County; Wilfley Leasing Co., Summit County; Axel Lind, Lake County; and The Ore & Chemical Corporation, Lake County.

---

[6] Information furnished by Foreign Economic Administration.

[7] Mineral Trade Notes, Confidential Series 21, March 1944, pp. 33-37.

Illinois.—The Midland Electric Coal Corporation produced 12,968 tons of pyrites (coal brasses) in Henry County in 1943.

Indiana.—The Snow Hill Coal Corporation shipped 3,906 long tons of pyrites (coal brasses) from its Talleydale mine in Vigo County, in 1943.

Montana.—Pyrite recovery in Montana in 1943 was limited to the flotation concentrates produced by Anaconda Copper Mining Co. as a byproduct at its copper-plant operations at Anaconda.

New York.—In 1943 New York produced 62,907 long tons of pyrites.

Pennsylvania.—The Bethlehem Steel Co. produced pyrites in Lebanon County.

Tennessee.—As usual, the output of the Tennessee Copper Co. in the Ducktown Basin, Polk County, made Tennessee the leading pyrites-producing State. These flotation concentrates are not sold as such but are converted into other products before being marketed.

Virginia.—In recent years pyrites have been produced in Virginia only by General Chemical Co., at the Gossan mine, Carroll County, and consumed by the company in its acid plant at Pulaski.

Wisconsin.—The Vinegar Hill Zinc Co. recovered a substantial tonnage of pyrites as a flotation concentrate in Grant County from ores produced at mines in the Platteville district.

FOREIGN TRADE

Owing to the elimination of one of the Canadian mines that has been replacing Spanish sources since 1939, imports from Canada were 30 percent lower than in 1942. Imports from Spain increased somewhat, so the over-all reduction was only 15 percent. At the year end the lost capacity had not been replaced in Canada.

Although Spanish pyrites were variously quoted in the trade journals from 12 to possibly 20 cents per long-ton unit of sulfur, c. i. f. United States ports, actual realization, limited by comparable prices of Canadian pyrite, was approximately 14 cents per unit.

Pyrites, containing more than 25 percent sulfur, imported into the United States, 1939–43, by countries

Country	1939		1940		1941		1942		1943	
	Long tons	Value	Long tons	Value	Long tons	Value	Long tons	Value	Long tons	Value
Canada	176,804	$470,336	81,157	$560,476	244,287	$1,151,964	282,897	$1,313,295	197,750	$683,110
Greece	22,800	106,271	--------	--------	--------	--------	--------	--------	--------	--------
Mexico	--------	--------	203	719	320	1,500	682	2,995	273	916
Spain	282,732	738,439	325,644	790,172	124,231	326,052	16,561	43,866	58,285	147,533

WORLD PRODUCTION

Lack of official statistics from most countries leaves much doubt as to what degree of success consumers have had in replacing tonnage formerly supplied by such large producers as Spain and Cyprus. From the meager information available, it seems likely that world production of pyrites did not exceed 9,000,000 metric tons in 1943 and may have been substantially less.

World production of pyrites (including cupreous pyrites), 1938, 1942, and 1943, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

[1] In addition to countries listed Belgium, Brazil, China, Chosen, Eire, India, Japan, and U. S. S. R. produced pyrites, but production data are not available.

[2] Data not available. [3] Slovakia only. [4] Estimate. [5] January to September, inclusive.

[6] Average sulfur content of pyrites was 42 percent in 1931, latest year for which such information is available.

Canada.—Canada is poor in sulfur and rich in pyrites so the tendency is to utilize pyrites even in the manufacture of sulfur compounds for the paper industry. Native sulfur has been preferred for this purpose in the past, but an improved plant using pyrites is now supplying a large part of the requirements of the St. Lawrence Paper Co. Also a plant has been installed recently by E. B. Eddy Co., Ltd.

Ten plants operating in Canada produced 578,474 tons of sulfuric acid in 1942.[8]

In 1943 the Aldermac mine closed down, having exhausted its ore body. This mine has been furnishing a large part of the Canadian pyrites exported to the United States, and exports probably will be sharply reduced, as no successor has yet appeared.

Germany.—Reports from Europe indicate that loss of access to some Mediterranean sulfur has inconvenienced but not crippled German industry. Although an acid shortage is believed to exist, most deficiencies have been filled by increased production of pyrites, recovery of byproducts, and regeneration of spent acid. Germany proper has rather large deposits of pyrites mixed with zinc blende in Meggen near Cologne. Smaller deposits of sulfur-bearing ores occur in Austria, Czechoslovakia, and Poland. Increased production is also believed to be coming from plants utilizing gypsum as a raw material. The Wolfen plant of I. G. Farbenindustrie resumed operation in 1937 and has been furnishing 80,000 tons of acid a year, using an improved process developed at Leverkusen. Gypsum is also being used instead of sulfuric acid to provide the sulfur content of ammonium sulfate in the Luena plant of I. G. Farbenindustrie in Saxony.[9]

Great Britain.—Historically, Great Britain has depended on imports of sulfur and pyrites, but shipping stringencies have focused attention on byproduct acid recovery and more recently on the extraction of pyrites from coal-mine waste. The sulfur in Britain's annual coal output is estimated to be about 2½ million long tons. Current British output of sulfuric acid is estimated to be over 2,000,000 long tons.[10]

Some encouragement was given pyrites-extraction plans by the Government Sulfuric Acid Control.[11]

Portugal.—Mason & Barry, Ltd., reported that 83,433 long tons of pyrites were raised from the mine in 1942; 42,995 long tons of pyrites and 14,909 tons of sulfur were shipped.[12]

Spain.—Export difficulties continued to restrict production of pyrites in Spain in 1943. Although sales to the United States were greater than in 1942, they totaled only a fraction of the 300,000 long-ton level common before the war.

Union of South Africa.—Although everyone involved agrees that maximum use of domestic pyrites is commendable, the acid consumers, principally the superphosphate producers, point out that transportation costs from the Rand mines to the Cape are so high that in peacetime importation of sulfur is more economical. An investigation revealed that ample quantities of pyrites are available, but the investigating committee decided that the time and expense required for the installation of new equipment were not warranted in the face of the fact that the superphosphate industry is not protected by tariffs. At present the plant at Unbogintwini, Natal, uses pyrites from West Rand Consolidated Mines, Ltd., and the plant at Somerset West, Cape Province, uses imported sulfur. About 33,000 long tons of pyrites are produced annually.[13]

GENERAL CONDITIONS

A new record for the marketed production of domestic phosphate rock was made in 1943, the quantity sold or used by producers reaching 5,126,232 long tons (see fig. 1), nearly half a million tons greater than the previous record, that for 1941. Florida was the only State showing an increase in sales. The value—nearly 2½ million dollars more than that of 1942—was less than that for 1920. Mined production reached a new high point in 1943—5,369,967 long tons. Exports continued to decline and dropped to 358,010 long tons, but imports rose sharply. Stocks in producers' hands at the end of the year were less than on December 31, 1942. Apparent domestic consumption reached new heights—17 percent above the previous record made in 1942.

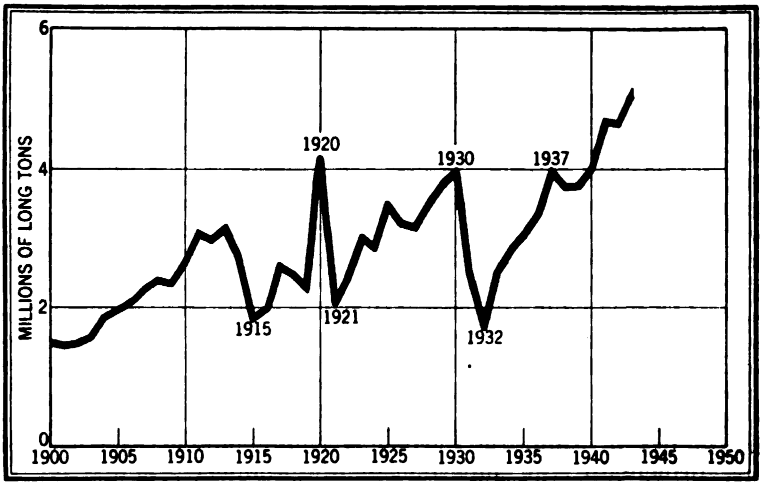

Figure 1.—Marketed production of domestic phosphate rock, 1900-1943.

The rated annual capacity of the phosphate fertilizer-manufacturing industry in the United States in 1943 is given by the Tennessee Valley Authority as 1,712,000 tons of P_2O_5.[1] For 1943, for the first time, the Bureau of Mines collected from the producers figures for the P_2O_5 content of the domestic production and sales of phosphate rock; these are given in the accompanying salient statistics table. The P_2O_5 content of domestic phosphate rock sold or used in 1943 was 1,654,493 long tons.

General papers published recently include those by McConnell,[2] Mitchell, Faust, Hendricks, and Reynolds,[3] Chapman,[4] and Jenkins.[5]

PRODUCTION

A new high record for phosphate rock mined in the United States was made in 1943, exceeding the previous high made in 1941 by 447,784 tons. Phosphate rock was mined in 1943 in Florida, Tennessee, Montana, and Idaho and apatite in Virginia.

[1] Includes small quantity of apatite from Virginia.
[2] Includes small quantity of phosphate rock from South Carolina.

SALES

The quantity of domestic phosphate rock sold or used by producers made a new high record in 1943 and exceeded the previous maximum of 1941 by nearly one-half million tons. The total value was nearly 2½ million dollars more than that of 1942 but was still about 6 million dollars below the record value of the boom year 1920. The average value per ton increased.

Phosphate rock sold or used by producers in the United States, 1939–43

Year	Long tons	Value at mines		Year	Long tons	Value at mines	
		Total	Average			Total	Average
1939	3,757,067	$12,294,042	$3.27	1942	4,644,240	$16,597,492	$3.57
1940	4,002,700	12,334,662	3.08	1943	5,126,232	18,962,021	3.70
1941	4,689,652	15,596,273	3.33				

DISTRIBUTION OF SALES

Nearly a third of the phosphate rock sold or used by producers in the United States in 1943 was of the 72-percent B. P. L. grade; all grades above this equaled about another third. Phosphate rock containing less than 60 percent B. P. L. continued to form an increasing part of the total sold or used and reached 11 percent of the total in 1943, or more than one-half million tons.

In 1943, 71 percent of the domestic phosphate rock sold or used by producers is reported to have gone into the manufacture of superphosphates. The quantity so used was more than a third of a million tons greater than in 1942. A sharp increase is reported in the quantity sold or used for the production of various chemicals; the quantity sold or used for direct application to the soil continued its upward trend, and that utilized for making stock and poultry feed jumped to 67,288 tons in 1943. A primary reason for this latter increase was a deficit in the supply of the usual phosphorus supplements for animal feed, principally bone meal, owing to the increased needs of the greater livestock production and the curtailment of imports of bone products. Detailed discussions of phosphate rock and phosphorus in animal feeds have recently appeared.[6] A list of the companies reporting phosphate rock sold or used in 1943 for the production of stock and poultry feed follows:

[1] Bone phosphate of lime.
[2] Figures not available.
[3] 0.5 percent or less.
[4] Includes grades of B. P. L. content 65.9, 68.2, 68.6, 68/69, 69, 69.2–69.4, 71, 73, 73.2, 73.3, 73.6, 73/74, 77 plus, 78, and above 85 percent; B. P. L. content not known for ground phosphate rock and dust in 1942.
[5] Includes some calcined phosphate and phosphatic material used in pig-iron blast furnaces, construction work, filter bed, parting compounds, research, refractories, in manufacture of concentrated fertilizers, and in minor uses not specified.
[6] As reported to Bureau of Mines by domestic producers.

CONSUMPTION

The annual apparent consumption of phosphate rock in the United States continued its abnormal rise under war conditions in 1943 and reached a new high record nearly 700,000 tons above the previous high in 1942. The annual consumption of phosphate rock in the United States from 1867 to 1943 is shown in figure 2. The effect of World War II upon domestic consumption is shown in the abnormal extension of the line showing consumption above the logistic curve indicative of the normal growth of consumption. The ever-increasing width of the fluctuations across this growth line since 1910 is worth serious consideration in any study of the future outlook for domestic demands.

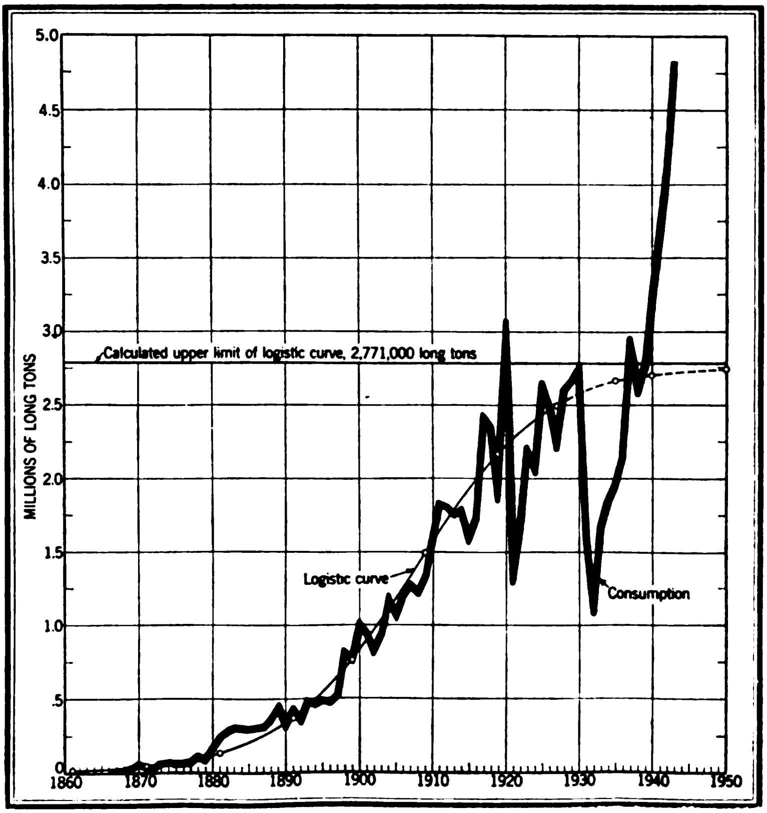

FIGURE 2.—Consumption of phosphate rock in the United States, 1867–1943.

PRICES

The ceiling prices per long ton of various grades of Florida and Tennessee unground phosphate rock are shown in the accompanying table. Maximum prices for Florida land-pebble phosphate rock and Tennessee brown-rock phosphate were established by the Office of Price Administration in a schedule issued October 13, 1942, effective October 19, 1942 (Maximum Price Regulation 240). An amendment to this regulation (M. P. R. 240, amendment 3) issued November 27, 1943, effective December 3, 1943, increased Tennessee producers' prices 20 cents a ton to compensate mine operators for wage increases granted to their employees. Pricing problems in the fertilizer industry were discussed by Gran of O. P. A.[7]

Ceiling prices per long ton of Florida and Tennessee unground phosphate rock, f. o. b. cars at mines, in 1943, by grades [1]

[2] Bone phosphate of lime.

During the fiscal year ended June 30, 1943, the Federal Trade Commission[8] made an inquiry into costs, prices, and profits in the fertilizer and related products industries. This inquiry was made at the request of the Office of Price Administration so that it might have the factual background for its price actions.

Information as to costs, prices, and profits was obtained with reference to the operations of 12 phosphate rock mines of 11 companies, and for the sulfuric acid, superphosphate and mixed fertilizer operations of 40 plants of 24 companies. From time to time, during the course of the inquiry, reports were prepared and forwarded to the Office of Price Administration with reference to these operations for the companies included in the inquiry.

The various reports on the results of the study contain financial data for individual companies for each of the years 1936–42, including rates of profit on investment and percentage of profit on sales. For the years 1941 and 1942, they include the details of the cost of production, the cost and profit per ton of product with reference to phosphate rock, sulfuric acid, superphosphate and mixed fertilizer, and the net realization from the sales of selected grades of fertilizer, analysis of purchases of fertilizer materials, and other related statistics.

REVIEW BY STATES

Florida.—New records were set in 1943 for the quantities of land pebble, soft rock, and total Florida phosphate rock sold or used (see fig. 3), whereas the quantity of hard rock marketed was less than half that in 1942. The total quantity of phosphate rock sold or used by producers in Florida was 219,109 tons more than the previous record, in 1920. The total value of the rock sold or used in 1943 was, however, over 7 million dollars less than in 1920. Soft-rock sales were much above the previous record high of 1937. The average values per ton for all types were higher in 1943 than in 1942. The P_2O_5 content (tonnage) of the various types of Florida rock sold or used is given in the salient statistics table—first table of this chapter.

[8] Federal Trade Commission, Annual Report for the Fiscal Year Ended June 30, 1943: 1943, 128 pp. (see pp. 23–24).

In 1943 hard-rock phosphate was mined only at the joint operations of C. & J. Camp, Inc., and J. Buttgenbach & Co. in sec. 22, Citrus County, about 3 miles from Hernando. The only other hard-rock-phosphate mining company—the Dunnellon Phosphate Mining Co., of Savannah, Ga.—did no mining in 1943 but shipped hard rock from stocks. Virtually all of the shipments of hard rock during the year were for export.

The mine and washer of the Pembroke Chemical Corporation, Pembroke, in the land-pebble field were shut down during the year; but the drying plant operated, and shipments of dried rock were made. The other seven companies usually operating in the land-pebble field—American Cyanamid Co., Brewster; American Agricultural Chemical Co., Pierce; Coronet Phosphate Co., Plant City; International Minerals & Chemical Corporation, Mulberry; Phosphate Mining Co., Nichols; Southern Phosphate Corporation, Ridgewood; and the Swift & Co. Fertilizer Works, Agricola—continued to mine and ship land pebble.

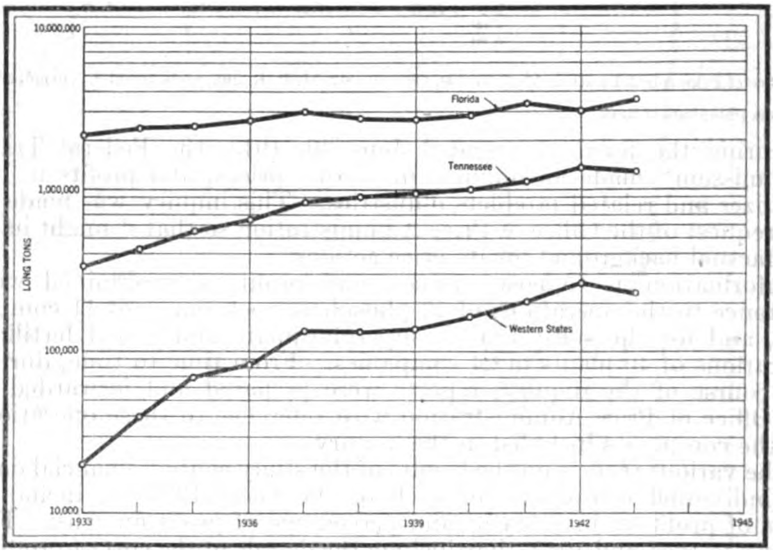

FIGURE 3.—Rate of growth of phosphate rock sold or used by producers, by States, 1933–43.

Stocks of Florida phosphate rock on December 31, 1943, as reported by producers, were down sharply from the previous year.

Taylor,[9] in the fifth article of a series, continued his description of current practices in the land-pebble phosphate-rock field.

The idle blast-furnace and sintering plant of the Pembroke Chemical Corporation, Pembroke, Fla.,[10] are to be dismantled and shipped to Rusk, Tex., for use in the production of charcoal iron from the brown iron ores of eastern Texas. This electrically operated blast furnace was originally built at Pembroke to produce elemental phosphorus from phosphate rock and coke.

Statistical data on re-treatment, between November 6, 1941, and April 19, 1942, of washer-waste accumulations at Mine No. 9 of the

International Minerals & Chemical Corporation have been published.[11]

Vernon[12] has called attention to the relationship between the Florida phosphate deposits and the Pleistocene terraces, different phosphate beds underlying separate terraces; some terraces in the land-pebble field have surface elevations 78, 94, 110, 121, and 212 feet above sea level.

The Dixie Phosphate Co., one of the several companies producing "colloidal" phosphate, leased its plant at Dunnellon, Fla., on October 22, 1943, to the Sea Board Phosphate Co., S. W. Corner Meadow and McKean Sts., Philadelphia 48, Pa., who operated it during the rest of the year.

Volk[13] has presented the results of a comparative study of the fertilizing value of waste-pond phosphates, phosphate rock, and superphosphate.

Florida phosphate rock sold or used by producers, 1939–43, by kinds

[1] Includes material from waste-pond operations.
[2] Includes sintered matrix.

Tennessee.—According to reports from the producing companies, the tonnage of phosphate rock sold or used by Tennessee producers in 1943 (plus a small quantity of apatite from Virginia) declined for the first time in many years. This slight reversal of a long established upward trend is indicated in figure 3. The phosphate rock sold or used—all brown rock, except for a little blue rock used by the Tennessee Valley Authority, withdrawn from its stocks, and the Virginia apatite—was nearly 60,000 tons less than in 1942. The total value was also less than in 1942 but still greater than in years immediately preceding. Stocks in the hands of the producers on December 31, 1943, showed a considerable increase over the quantity on hand at the close of 1942. The P_2O_5 contents (tonnages) of the phosphate rock mined, of that sold or used and of the stocks are given in the salient statistics table—first table of this chapter.

[1] Separate figures for brown rock and blue rock cannot be given without disclosing confidential data regarding blue-rock production.
[2] Includes a small quantity of blue rock.

Tennessee brown-rock phosphate was mined in 1943 by the Tennessee Valley Authority and the following private companies: Armour Fertilizer Works, Federal Chemical Co., Gilbreath & Pressnell, Harsh Phosphate Co., Hoover & Mason Phosphate Co., International Minerals & Chemical Corporation, Monsanto Chemical Co., and the Virginia-Carolina Chemical Corporation.

The International Minerals & Chemical Corporation, in its annual report for the fiscal year ended June 30, 1943, states that additional reserves of phosphate rock were acquired by purchase during the year and that the shipments from its Tennessee mines in the year covered by the report were the largest in the corporation's history.

Operations of the Monsanto Chemical Co. were described in an article by Robbins.[14]

According to the annual report of the Tennessee Valley Authority for the fiscal year ended June 30, 1943, a total of 253,840 tons of phosphatic materials, all from deposits in Tennessee, was received at Muscle Shoals during the fiscal year. Large-scale operation of the Authority's field phosphate plants in middle Tennessee got under way, although necessary changes and substitutions in experimental units reduced deliveries below the quantity anticipated. Shipments from the field plants totaled 117,000 dry net tons, of which 89,000 tons were used in phosphate operations. The latter amount corresponds to about one-third of the quantity consumed during the period. By the close of the fiscal year the field plants were supplying approximately two-thirds of the total tonnage of phosphate needed for operation of the Muscle Shoals plant; the remainder was being purchased.

During the year the Tennessee Valley Authority acquired additional phosphate reserves in Tennessee, including mineral rights on deposits containing an estimated 5,167,000 tons of minable phosphate and an estimated 893,000 tons of minable phosphate on land acquired in fee simple. The net increase in the Authority's phosphate reserves—new reserves acquired minus 214,000 tons mined—was 5,846,000 tons—an increase in the total reserve of 22,100,000 to 28,000,000 tons of minable phosphate.

Military demands for elemental phosphorus took approximately two-thirds of the entire Authority production of 18,900 tons during the fiscal year 1943, and somewhat more than one-fifth of the military supply was provided for lend-lease shipment. During the year, the Authority completed conversion of all of its phosphorus electric furnaces but one to production of munition-grade elemental phosphorus. One furnace produces phosphoric acid directly.

---

[14] Robbins, W. C., Phosphorus from the Red Clay of Tennessee: Excavating Eng., vol. 37, No. 8, August 1943, pp. 384-387, 409.

Although somewhat more than 6,000 tons of phosphorus not immediately demanded by the War Department were used in manufacture of concentrated superphosphate and calcium metaphosphate, the over-all production of these plant foods represented a sharp reduction for the second year in succession. At the same time much less was available for domestic agricultural use because 54,000 of the 77,300 tons of concentrated superphosphate shipped from Muscle Shoals was provided for lend-lease. Actual production was about 60,200 tons of concentrated superphosphate and 7,300 tons of calcium metaphosphate.

Approximately 4,700 additional farms joined the Authority's test-demonstration program during the fiscal year 1943. This brought the number that has participated from the beginning to about 44,000, of which about 30,000, scattered through 862 counties in 29 States, were active participants on June 30, 1943.

At the close of the fiscal year 1943 the Authority was preparing to produce 15,000 tons of dicalcium phosphate during the fiscal year 1944, for direct feeding to stock as a substitute for bone meal in the present scarcity of that source of phosphorus for mineral supplements of animal feed.

Virginia.—The Southern Mineral Products Corporation, a subsidiary of the Vanadium Corporation of America, operated its Piney River nelsonite deposit during most of 1943, disposing of the apatite and ilmenite concentrates recovered at its mill to the adjacent plant of the Virginia Chemical Corporation. The ilmenite was used in the manufacture of titanium dioxide and the apatite in the production (during the early months of 1943) of monocalcium phosphate. Manufacture of this latter chemical was discontinued in July 1943, and the apatite later was used for making defluorinated phosphate. The Virginia Chemical Corporation, a wholly owned subsidiary of Interchemical Corporation, purchased the physical assets of the Southern Mineral Products Corporation on December 22, 1943. Early in 1944 the company was manufacturing titanium dioxide, sulfuric acid, ferrous sulfate, defluorinated phosphate, and hydrated yellow ferric oxide.

Western States.—The marketed production of Western States phosphate rock experienced a set-back in 1943 of 14 percent from the record total reached in 1942 (see fig. 3). The total value was slightly more than a million dollars. The output in 1943 came from Idaho and Montana; Utah was inactive. The average P_2O_5 content of Western States phosphate rock sold or used in 1943 is reported as 31.80 percent.

Idaho rock sold or used in 1943 was about 5 percent less than the record production for 1942. The same two companies were active in this State as in 1942. By far the larger of these, the Anaconda Copper Mining Co., operated its No. 3 mine at Conda, Caribou County. Most of the Conda shipments in 1943 went to Anaconda, Mont., for conversion to superphosphate. Much smaller quantities were used for the production of phosphate chemicals, for direct application to the soil, for animal feed, and for fertilizer filler. Some was exported. The other producer (the Teton Phosphate Co., Boise) shipped phosphate rock from its holdings in Bear Lake County near Montpelier. Most of this material was sold for direct application to the soil. A small quantity was shipped for use in animal feeds.

The geologic features of eastern Idaho and western Wyoming are described in a paper by Nelson and Church.[15]

Montana was the largest phosphate-rock producer of the Western States group in 1943 as in 1942 (see fig. 4), although its lead in sales was not nearly as great as in 1942. Its sales in 1943 were 20 percent less than the record made in 1942. Montana had but one producing company in 1943—the Montana Phosphate Products Co. of Trail, British Columbia. This company operated the Anderson mine near Garrison, as well as several Federal leases in Powell County. It leased the property of the Mineral Hill Mining Co. near Avon, Powell County, on July 7, 1943, and operated it after that date. Most of the product of these various operations was exported to the Consolidated Mining & Smelting Co. of Canada at Trail. A considerable amount, however, was sold in the United States. The Mineral Hill Mining Co. did not operate its property in 1943 before leasing it. L. H. Skeels, who shipped a small quantity of phosphate rock from a property near Maxville, Granite County, in 1942, did not operate in 1943. The International Minerals & Chemical Corporation, which in 1942 acquired the Federal lease of the Northwestern Improvement Co., St. Paul, Minn. (Great Falls Serial No. 077838) conducted some exploratory work on the property in 1943 but did no mining on a commercial basis.

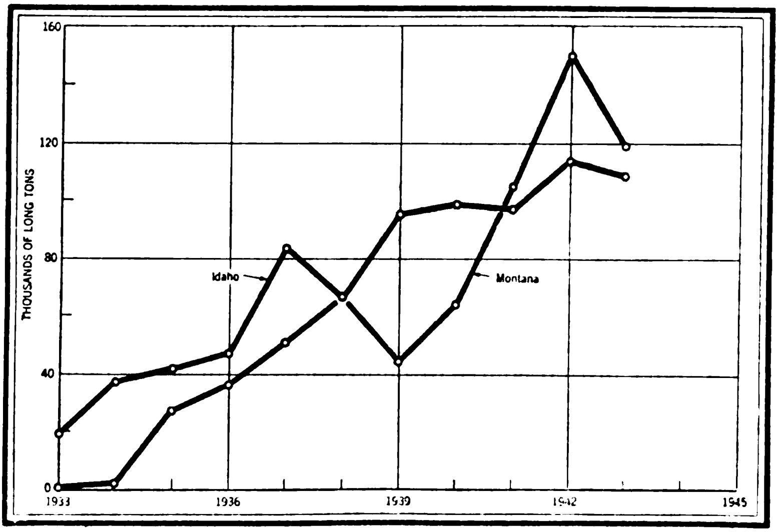

FIGURE 4.—Idaho and Montana phosphate rock sold or used by producers, 1933–43.

No phosphate-rock production was reported from Utah in 1943.

[15] Nelson, V. E., and Church, Victor., Critical Structure of the Gros Ventre and Northern Hoback Ranges, Wyoming: Jour. Geol., vol. 41, No. 3, April-May 1943, pp. 143–166.

The Garfield Chemical & Manufacturing Corporation, Salt Lake City, Utah, which mined and shipped in 1942 from Federal-leased land near Spanish Fork, Utah County, for use in pig-iron blast furnaces, did not report any operations on this leased ground in 1943.

The average value per ton of the Western States phosphate rock sold or used, as reported by producers to the Bureau of Mines, increased sharply from $4.11 in 1942 to $4.59 in 1943. The increase per ton was 68 cents in Idaho and 27 cents in Montana.

Western States phosphate rock sold or used by producers, 1939–43

FOREIGN TRADE [16]

Imports.—Considerable quantities of both apatite and phosphate rock were imported in 1943. Apatite imports totaled 6,114 long tons compared with 179 tons in 1942. All came from Soviet Russia. Phosphate-rock imports in 1943 were over 10 times those in 1942, owing largely to the importation of phosphate rock from French North Africa early in the year following the capture of this area by the Allied Nations late in 1942. French Morocco furnished 33,779 tons and Algeria 1,000 tons. In addition to the above, 4,112 tons were imported from Curaçao and 1,500 tons are reported to have come from the Union of South Africa.

In June 1943, an agreement is reported to have been put into effect by the Lend-Lease Administration, the Combined Food Board, and the Combined Raw Materials Board whereby supplies of North African phosphate rock would be shipped only to Spain, Portugal, Switzerland, and England.

Exports.—The quantity of phosphate rock exported from the United States in 1943 was even less than in 1942 and apparently reflects the recent availability of North African phosphate rock for

---

[1] Includes Florida high-grade hard rock and Tennessee, Idaho, and Montana phosphate rock.

Other phosphate materials[1] *exported from the United States, 1939–43*

Year	Long tons	Value	Year	Long tons	Value
1939	29,080	$192,306	1942	5,257	$292,934
1940	11,924	201,047	1943	862	94,391
1941	22,988	262,045			

---

[1] Includes bone ash, dust, and meal; animal carbon for fertilizer; basic slag; sintered matrix, etc.

WORLD PRODUCTION

Figures for the production of phosphate rock in most foreign countries in 1943 are not yet available, nor (with the exception of French North Africa) [17] is much information obtainable regarding the foreign phosphate-rock industries. Several of the Japanese-held phosphate islands in the Pacific, including Nauru and Angaur Islands and the apatite workings near Laokay in French Indochina, were bombed by the Allies in 1943 and early in 1944.

World production of phosphate rock, 1939–43, by countries, in metric tons [1]

SUPERPHOSPHATES

Superphosphate, as a phosphatic fertilizer itself and also as the phosphate-bearing component in mixed and complete fertilizers, has naturally responded to the great war demand for fertilizers, now the highest of all time. Production and sales have increased much above pre-war times, and the industry has taken greatly augmented quantities of phosphate rock to produce the quantities needed. Imports of normal and concentrated superphosphates have declined; but in 1943, imports of the ammoniated variety, although small, were greater than in the previous 2 years. Exports markedly increased in 1943 over 1942, owing to larger shipments to Canada and the United Kingdom.

The following tables give outstanding features of the superphosphate industry of the United States in recent years.

Salient statistics of the superphosphate industry in the United States, 1941–43

	1941	1942	1943
Production [1] short tons	4,326,402	5,144,484	6,292,955
Shipments,[1] total do	3,633,871	3,961,362	3,935,293
To mixers do	1,638,026	1,916,772	3,935,293
To other acidulators (including exchange transfers) do	659,514	541,225	
To all others (including Government agencies) do	1,336,331	1,503,365	
Stocks in manufacturers' hands, Dec. 31 [1] do	932,683	[2] 973,224	791,385
Exports of superphosphates [3] long tons	146,875	165,092	239,779
Imports of superphosphates [3] do	17,368	16,659	2,554
Sales of phosphate rock by producers for superphosphate production long tons	2,825,456	3,242,689	3,631,786

Superphosphates (acid phosphates) imported for consumption in the United States, 1941–43, by classes [1]

Class	1941		1942		1943	
	Long tons	Value	Long tons	Value	Long tons	Value
Normal (standard) (not over 25 percent P_2O_5 content)	12,017	$172,990	5,965	$80,409	252	$4,678
Concentrated (treble) (over 25 percent P_2O_5 content)	5,333	133,835	10,694	300,342	2,242	63,515
Ammoniated	18	376			60	3,698
	17,368	307,201	16,659	380,751	2,554	71,891

[1] All from Canada.

Several articles relating to the superphosphate industry appeared in 1943.[19]

BASIC SLAG

No recent figures for the production of basic slag are available, either for the United States or for foreign countries. Only 3 long tons were imported into this country in 1943.

TALC, PYROPHYLLITE, AND GROUND SOAPSTONE[1]

By Bertrand L. Johnson and F. M. Barsigian

SUMMARY OUTLINE

	Page		Page
General conditions	1431	Prices	1434
Salient statistics	1432	Developments in the industry	1435
Post-war outlook	1433	Foreign trade	1436
Sales	1433	World production	1438
Markets	1434		

GENERAL CONDITIONS

Increases in demands from paint, rubber, paper, insecticide, and foundry-facings industries for talc, pyrophyllite, and ground soapstone raised both mined production and sales in 1943 to levels higher than those of 1942. Sales gained 6 percent and the total value 8 percent, setting a new high record. (See fig. 1.) Only sales of crude material decreased in quantity, and only the sales of ground products increased in value. Imports declined in 1943, although the quantity

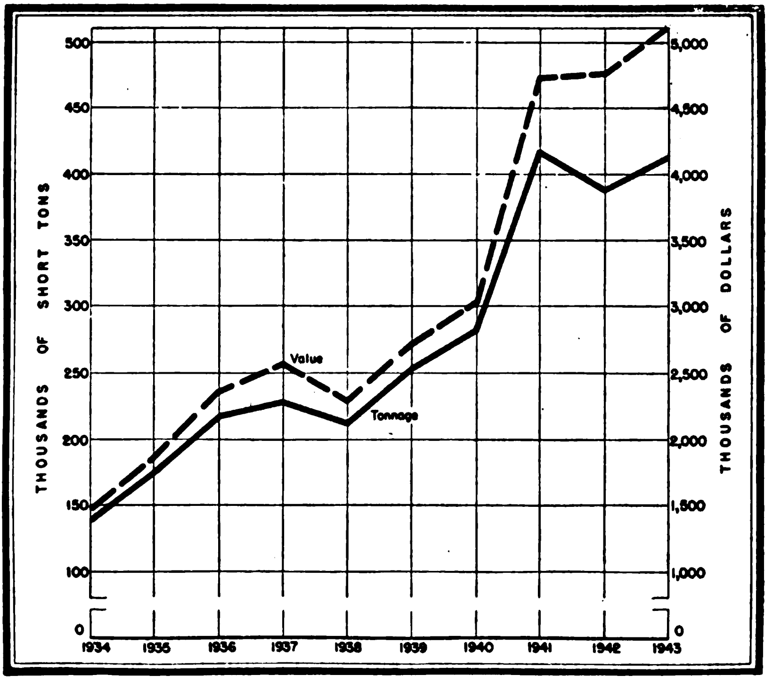

FIGURE 1.—Sales of domestic talc, pyrophyllite, and ground soapstone, 1934–43.

---

[1] Soapstone sold in slabs or blocks is included in the chapter on Stone.

of crude brought in was higher than in 1942. Exports were higher in both quantity and value.

Pyrophyllite is included with talc in this chapter because of its resemblance to talc in certain physical properties and because it is interchangeable with talc in some uses, although during recent years certain specialized uses for pyrophyllite have been developed. It is a hydrous aluminum silicate, whereas talc is a hydrous magnesium silicate. Production and sales figures for pyrophyllite for 2 years are now available.

Salient statistics of the talc, pyrophyllite,[1] and ground-soapstone industries in the United States, 1942–43

	1942		1943	
	Short tons	Value	Short tons	Value
Mined:

	....	870, 213	....	992, 292

[1] In 1942: Mined, 53,247 short tons. Sold—crude, 6,440 tons, $35,790; ground, 47,229 tons, $379,026; total, 53,669 tons, $414,816. In 1943: Mined, 64,198 short tons. Sold—crude, 5,432 tons, $34,306; ground, 56,710 tons, $460,485; total, 62,142 tons, $494,791.

[2] Data not available.

[3] Includes pinite from Nevada.

[4] Exclusive of "manufactures, n. s. p. f., except toilet preparations," as follows: 1942, $2,704; 1943, $20. Quantities not available.

[5] Less than 1 ton.

[6] Quantity not recorded.

Twelve States reported sales of talc, pyrophyllite, or ground soapstone in 1943. Alabama, which entered the ranks of talc producers in 1942, had no production in 1943, nor was any pinite reported from Nevada. The Eastern States furnished 81 percent of total domestic sales in 1943.

Steatite talc has been controlled by War Production Board Conservation Order M–239, issued October 13, 1942. This order was amended February 6, 1943, and on April 29, 1943. The order was revised again on March 28, 1944, when inventory restrictions on steatite talc were relaxed; whereas those on other talcs were unchanged, except for New York State varieties, which were made more rigid.

The Metals Reserve Co. stock-piled steatite talc in 1943.

A description of a talc deposit in Nevada was published during the year.[2]

---

[2] Bureau of Mines, Reed Talc Property, Esmeralda County, Nevada: War Minerals Report 115, 1943, 7 pp.

POST-WAR OUTLOOK

The wide diversity of uses of talc, pyrophyllite, and ground soapstone undoubtedly will cushion any decline in total production and sales resulting from the cessation of World War II. Sales for certain war-stimulated uses, such as nonreflecting paints, radio insulators, insecticides, and foundry facings, may be expected to drop considerably, but sales for many other uses of these commodities may increase with the return to a peacetime economy. Competition of foreign talcs unquestionably will be felt from a revived import trade in talc of steatite and cosmetic grades.

SALES

In 1943, both the quantity and value of domestic talc, pyrophyllite, and ground soapstone sold or used were greater than in 1942, according to the report of the producers to the Bureau of Mines, but the tonnage did not equal that sold or used in 1941; the total value, however, because of an increase in the average value, reached a new all-time record of over 5 million dollars.

Talc, pyrophyllite,[1] *and ground soapstone sold by producers in the United States, 1939–43, by classes*

Year	Crude			Sawed and manufactured		
	Short tons	Value at shipping point		Short tons	Value at shipping point

[1] In 1942: Crude, 6,440 tons, $35,790; ground, 47,229 tons, $379,026; total, 53,669 tons, $414,816. In 1943: Crude, 5,432 tons, $34,306; ground, 56,710 tons, $460,485; total, 62,142 tons, $494,791.

[2] Includes pinite from Nevada.

Sales by States.—In 1943, New York remained the leading producer. Its sales were more than double those of any other State but were slightly less than in 1942. The total quantity of North Carolina talc, pyrophyllite, and ground soapstone sold or used in 1943 was 15 percent above 1942 and exceeded the previous high in 1941. Georgia also made a new high record in sales in 1943, 18 percent above the high mark of 1942. Sales from California increased 12 percent but remained below the record high of 1941. North Carolina was the only State marketing pyrophyllite; the quantity sold or used in 1943 exceeded that of 1942.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1942–43, by States

State	1942		1943	
	Short tons	Value	Short tons	Value
California	51,649	$678,906	58,003	$912,291

[1] Included under "Other States"; Bureau of Mines not at liberty to publish figures separately.

[2] Includes pinite.

[3] Includes pyrophyllite from North Carolina as follows: 1942, 53,669 tons, valued at $414,816; 1943, 62,142 tons, valued at $494,791.

[4] 1942: Alabama, Montana, New Mexico, Pennsylvania, and Virginia. 1943: Maryland, Montana, New Mexico, Pennsylvania, and Virginia.

MARKETS

Six industries—paint, ceramics, rubber, roofing, paper, and insecticides—took 81 percent of the domestic sales of talc, pyrophyllite, and ground soapstone in 1943, according to reports from producers to the Bureau of Mines. Of these six, the rubber and insecticide industries alone showed percentage increases. Quantitatively the paint, rubber, paper, and insecticide industries increased their consumption.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1942–43, by uses

Use	1942		1943	
	Short tons	Percent of total	Short tons	Percent of total
Paint	125,518	32	129,238	31
Ceramics	48,372	13	47,900	12
Rubber	40,487	10	48,994	12
Roofing	48,870	13	47,500	12
Paper	30,440	8	34,449	8
Toilet preparations	18,902	5	17,682	4
Insecticides	15,810	4	24,462	6
Foundry facings	7,822	2	10,348	3
Crayons	1,474	(1)	1,446	(1)
Other uses reported [2]	27,631	7	29,528	7
Use not reported	22,637	6	21,321	5
	[3] 387,963	100	412,868	100

[1] Less than 0.5 percent.

[2] 1942: Refractory, chemical war service, insulation, plastics, bleaching, textile, lubricants, and other minor uses; 1943: Chemical war service, refractory, plaster, insulation, bleaching, mine dust, textile, and other minor uses.

[3] Includes pinite.

PRICES

Quoted prices on ground domestic talc per ton, f. o. b. works, have not changed from those given in the Talc, Pyrophyllite, and Ground

Soapstone chapter in Minerals Yearbook, 1942 (p. 1385). According to the Oil, Paint and Drug Reporter of May 8, 1944, these prices were:

California: $17.50 to $43.
New York:
  Fibrous, coarse, off color, $13.
  Fine, 325-mesh, 93 to 94 percent, $13 to $18; 98 to 99.5 percent, $15.25 to $19.25; 99.85 to 99.95 percent, $17 to $21.
Pennsylvania: $11 to $13.50.
Vermont: $14.
Canadian talc, bags, carlots, per ton, $24 to $30.

The prices on pyrophyllite quoted in the same journal were: Standard, 200-mesh, carlots, paper bags, mines, per ton, $10; 325-mesh, same basis, ton, $13; No. 3, 200-mesh, carlots, mines, ton, $8; 325-mesh, same basis, $11.

In an amendment to MPR No. 188 effective December 8, 1943, the Office of Price Administration authorized producers making sales of pyrophyllite and purchasers for resale to add not exceeding 40 cents per net ton to their established maximum f. o. b. prices. (Amendment 20 to Order A–1 under Maximum Price Regulation No. 188.)

On January 15, 1944, producers of talc and ground soapstone, including crayons, who are unable to maintain production under existing maximum prices were provided a method of applying for increased ceiling prices whenever a shortage exists or threatens. (Office of Price Administration, Amendment 10 to Order A–2 under Section 1499.159b of Maximum Price Regulation No. 188, effective January 15, 1944.)

The average values of all grades of talc, pyrophyllite, and ground soapstone in the past 5 years, as reported to the Bureau of Mines by producers, are given in the table under Sales.

DEVELOPMENTS IN THE INDUSTRY

A comprehensive study of pyrophyllite issued by the R. T. Vanderbilt Co.[3] presents the results of an investigation of pyrophyllites from its deposits at Glendon, Staley, and Stem, N. C., and points out the essential differences in the various types and the properties that make them suitable for use in whitewares.

According to Goudge,[4] experiments are now under way in the laboratories of the Canadian Bureau of Mines to develop the use of magnesia from brucite as a substitute for talc in special porcelain bodies that possess a low coefficient of thermal expansion and to ascertain its suitability for enriching steatite electrical insulation bodies in magnesia.

Ultra-violet light has been used [5] for the rapid evaluation of samples of talc.

Talc has recently been suggested as a fertilizer material for use in supplying magnesium to soils deficient in that element.

A standard for the production of identical steatite radio insulators has been adopted, which covers procurement methods, standard practices, manufacturing tolerances, and other factors.[6]

Siegal, Smith, and Greenburg[7] have made studies of the dust hazards at the tremolite-talc mines and mills of St. Lawrence County, N. Y.

Ueltz[8] has presented the results of a study of certain steatite bodies.

A recent comprehensive report by Stone[9] on ceramic materials for radio use includes data on raw materials for steatite ceramic insulators, their location, mining, and milling; thermal decomposition of talc; physical chemistry of steatite body composition, practical insulator-body compositions, and the processes of manufacture of the insulator bodies.

In another paper, Stone[10] discusses the physical changes of steatite ceramics under firing conditions.

Semmelman and Watts[11] and Lennon and Watts[12] presented the results of studies involving the use of talc in steatite porcelains.

Kane and Ueltz[13] reported the results of a study of iron-bearing talcs from Georgia, Maryland, Alabama, New York, and California, and soapstone from Vermont.

Western talcs—from California, Nevada, and Montana—were discussed by Roff.[14]

The use of the electron microscope in studying steatite ceramics is described by Kedesdy.[15]

A detailed description of the mining and treatment of talc by the three companies operating in northern Georgia is given by Hubbell[16] in an article published late in 1942.

Several papers[17] have been published dealing with the investigation by the Bureau of Mines of domestic talc resources for a grade suitable for the manufacture of ceramic radio insulators. A few talcs in various localities were found to be of proper grade as they occurred, but most of the samples required beneficiation.

FOREIGN TRADE[18]

Imports.—The declining trends of recent years in quantity and value of total imports of talc, steatite or soapstone, and French chalk continued in 1943, a decrease of 26 percent being recorded in the quantity and 25 percent in value from corresponding 1942 figures. As usual the imports were nearly all of materials "ground, washed, powdered, or pulverized, except toilet preparations;" these came from Canada and India. (See fig. 2.)

Steatite-talc imports are controlled by General Imports Order M–63.

Exports.—The quantity of "talc, steatite, soapstone, and pyrophyllite, crude and ground" exported from the United States was greater in 1943 than in 1942 but failed to reach the all-time record of 1941, but the value in 1943 was considerably greater than in 1941. The value of "powders—talcum (in packages), face, and compact" exported in 1943 was more than that of 1942.

Talcum and other powders exported from the United States, 1939–43

Year	Description	Short tons	Value	
			Total	Average
1939	Talc, steatite, and soapstone, crude and ground	9,047	$162,426	$17.95
	Powders—talcum (in packages), face, and compact	(1)	1,115,176	
1940	Talc, steatite, and soapstone, crude and ground	9,402	167,992	17.87
	Powders—talcum (in packages), face, and compact	(1)	945,530	
1941	Talc, steatite, soapstone, and pyrophyllite, crude and ground	10,889	216,440	19.88
	Powders—talcum (in packages), face, and compact	(1)	1,229,280	
1942	Talc, steatite, soapstone, and pyrophyllite, crude and ground	9,246	191,900	20.75
	Powders—talcum (in packages), face, and compact	(1)	678,313	
1943	Talc, steatite, soapstone, and pyrophyllite, crude and ground	10,693	236,268	22.10
	Powders—talcum (in packages), face, and compact	(1)	756,024

[1] In addition to countries listed, talc or pyrophyllite is reported produced in Brazil, Bulgaria, U. S. S. R. and Western Australia, but data on production are not available.
[2] Data not available.
[3] Excludes soapstone, which is reported only by value and was as follows: 1937, $40,513; 1938, $35,038; 1939, $41,471. Soapstone is sold in the form of both blocks and powder.
[4] January to September, inclusive.
[5] Includes steatite, as follows—1937: 500 tons; 1938: 3,480 tons; 1940: 17,191 tons; 1941: 18,948 tons.
[6] Talc, pyrophyllite, and ground soapstone sold by producers; includes also pinite in 1940, 1941, and 1942.
[7] January to June, inclusive.

Canada.—Canadian talc and soapstone developments in 1942 have been described as follows:[19]

> The entire talc and soapstone production of Canada has for some years past come from Ontario and Quebec. More than 90 percent of the total output of talc to the end of 1942, however, came from the Madoc area, Hastings County, Ontario, which supplies ground talc of good white colour, while Quebec produces mainly a grey, off-colour grade. Quebec is the only producer of cut soapstone blocks and bricks and of sawed crayons.
>
> Development of the Madoc deposits commenced about 1900 and total output to date is estimated to have been about 400,000 tons. Since 1937, Canada Talc Limited, operating the Conley mine, has furnished most of the supply. * * *. Production is at the rate of about 15,000 tons a year. * * *. In 1941, Trent Mining Syndicate commenced development on a property adjoining the Conley mine and erected a small mill, but was inactive during most of 1942. W. C. Spry (Victory Talc) continued to grind a small tonnage of off-colour talc in the mill of the Canada Slate Products about a mile north of Madoc, the crude rock being obtained from a deposit near Ompah, Frontenac County. * * *.
>
> Quebec has been producing cut soapstone since 1922, mainly in the form of blocks and bricks for the alkali recovery furnaces of domestic kraft mills. The sawing of crayons was commenced a few years ago. The industry is centered in the Thetford Mines district, Eastern Township, where Broughton Soapstone & Quarry Co. is the principal operator. This company operates two soapstone quarries near Leeds station in Broughton Township and, in addition to turning out cut stone and crayons, produces most of the ground talc made in the province. Other smaller operators in the same district are Charles Fortin, of Robertson, and L. C. Pharo, of Thetford Mines, working in Thetford and Leeds Townships,

[19] Canada, Department of Trade and Commerce, The Talc and Soapstone Industry, 1942: Dominion Bureau of Statistics, Mining, Metallurgical, and Chemical Branch, Ottawa, Canada, 1943. (Data from report by the Bureau of Mines, Ottawa.)

> respectively. Some of the sawing dust from these operations is sold to domestic roofing firms, and a considerable tonnage of quarry and sawing waste is shipped to the grinding plant of Pulverized Products, Limited, 4820 Fourth Ave., Rosemount, Montreal. Total sales of cut stone from the district in 1942 were about 3,000 tons and of ground talc about 8,500 tons. Baker Mining & Milling Co., 4010 St. Catherine Street, West, Montreal, the only other operator in Quebec, has a mine and mill near Highwater in Brome county, close to the Vermont boundary. * * * Total production of ground talc in the Province in 1942 was nearly 14,000 tons.

Late in 1943,[20] development of a long-known deposit of lava-grade talc in the Kootenay National Park, British Columbia, was begun. This is said to be the only known source of lava-grade talc in Canada and belongs to the Canadian Government.

A flotation process devised by the Canadian Bureau of Mines renders possible the beneficiation of Madoc talc with the production of a talc that can be used in the manufacture of steatite insulators for high-frequency radio purposes.[21]

Formation of a Government-owned company, Canadian Steatite Co., Ltd., of Georgetown, Ontario, is reported, the entire output of which is to be used by the Government.[22]

Newfoundland.[23]—Important pyrophyllite deposits are known in Newfoundland, from which some shipments were made a few years ago to the grinding mill of Clinchfield Sand & Feldspar Corporation, Baltimore, Md. At present, the deposits are owned and operated by Industrial Minerals Co. of Newfoundland, Ltd., Box 435, St. Johns, which in 1942 installed a grinding plant with a capacity of 25 tons a day and shipped about 500 tons of ground material to Great Britain.

FLUORSPAR

SUMMARY

Despite the many difficulties of operation in 1943 the fluorspar industry established an impressive record in supplying the unprecedented demand for this mineral, which is essential in the manufacture of steel, aluminum, high-octane gasoline, insecticides, and many other commodities necessary for the successful prosecution of the war. Production and shipments (433,000 and 406,016 short tons, respectively) in 1943 were 28 and 13 percent greater than in 1942, the previous record year, and shipments were 54 percent more than in 1918, during World War I. Moreover, production and shipments were 11 and 4 percent, respectively, greater than consumption in 1943, which also reached an all-time high. Illinois not only maintained its rank as the chief producing State by shipping 23 percent more fluorspar than in 1942, the previous record year, but supplied 49 percent of the total shipments in 1943. Colorado and New Mexico also established new records in 1943. On the other hand, shipments from Kentucky declined for the second successive year and were 18 percent less than in 1942. Shipments by river or river-rail (49,913 tons) were 37 percent less than the all-time high of 1942. Imports in 1943 (43,570 tons) were 20 times those of 1942 and the largest since 1930. Exports—usually small—were only slightly higher than in 1942.

Despite the record production of fluorspar in 1943, the output of metallurgical grade lagged behind consumption during the first half of the year; consequently, inventories at consuming plants declined progressively until the end of June. Although supplies of fluorspar were not allocated, beginning January 1943 shipments of both metallurgical and ceramic grades were controlled by the War Production Board, which forbade any supplier to ship fluorspar to consumers having an inventory greater than a "practicable working minimum." Moreover, because of the scarcity of metallurgical-grade fluorspar, steel manufacturers were urged to use this grade sparingly and where possible to use flotation concentrates, the supply of which exceeded demand. That the domestic steel industry cooperated in complying with these requests is evidenced by the fact that the average consumption of fluorspar per long ton of basic open-hearth steel produced dropped from 6.4 pounds in 1942 to 5.9 pounds in 1943, and purchases of flotation concentrates totaled 3,638 tons. The flotation concentrates were used chiefly in basic electric steel furnaces. Some open-hearth operators experimented with flotation concentrates, but results were not entirely satisfactory, probably because of the fine size of the concentrates. Nevertheless, one operator found that a three-way mixture of 50 percent iron sinter, 30 percent gravel fluorspar, and 20 percent flotation concentrates proved satisfactory. The smaller consumption at steel plants resulted mainly from conservation measures, notwithstanding the fact that lower-grade fluorspar was used. Possible substitutes, such as ilmenite, sodium chloride, topaz, soda-ash briquets, and bauxite, were under study, but so far as known the use of these materials as substitutes for fluorspar was insignificant. However, it was reported that a considerable saving in fluorspar resulted from the increased use of roll scale. According to Norris,[2] "It appears at this time that the greatest saving of spar can be made by properly mixing fine roll scale with spar. Most heats can be shaped up with this mixture and at a net saving of spar."

---

[1] Figures on imports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the United States Department of Commerce; those on exports of fluorspar supplied by the producers.

Salient statistics of fluorspar in the United States, 1934–43, in short tons

Year	Shipments from domestic mines	Foreign trade		Consumption	Stocks at end of year

[1] Finished fluorspar only.

Contrary to expectation, the increase of $5 a ton in maximum prices for metallurgical-grade fluorspar, which became effective on November 23, 1942, did not stimulate production. Consequently, effective July 1, 1943, the base price was again advanced $5 a ton to $30 to $33, according to calcium fluoride and silica content. Concurrently, an average wage raise of about 24 percent was granted mine employees, and a uniform wage scale was put into effect for various classes of surface and mine labor in the Illinois-Kentucky district. The wage scale in Kentucky is 10 cents an hour less than in Illinois. Moreover, effective August 30, 1943, deliveries of the higher grades of metallurgical fluorspar were controlled by the War Production Board. These actions were followed by a marked improvement in production of metallurgical-grade fluorspar, which exceeded consumption for the remainder of 1943.

---

[2] Norris, F. G., The Open-Hearth in 1943: Blast Furnace and Steel Plant, vol. 32, No. 1, January 1944, p. 75.

Production of ceramic and acid grades was more than adequate to meet requirements in 1943; however, the consumption of acid grade was advancing at a more rapid rate than production and was only slightly less than production during the latter half of 1943. The base prices for ceramic and acid grades were increased to $37 a ton on July 1, 1943.

Deliveries of fluorspar to consumers in the United States totaled 404,658 short tons in 1943 (388,902 tons from domestic mines and 15,756 tons from foreign sources); in addition, 35,884 tons of finished fluorspar (8,070 tons from domestic mines and 27,814 tons from foreign sources) were delivered to Government stock piles. In 1942 deliveries to consumers totaled 353,469 tons (351,300 tons from domestic mines and 2,169 tons from foreign sources); there were no deliveries to Government stock piles in 1942. Total deliveries to steel plants in the United States increased to 236,425 tons in 1943 from 225,502 tons in 1942, and those to domestic manufacturers of hydrofluoric acid advanced to 123,820 tons from 89,983 tons; sales to the glass and enamel trades declined moderately.

The average composite selling price ($29.35 a short ton) of all grades of fluorspar (both domestic and foreign) delivered to consumers in the United States was $4.69 more than in 1942 ($24.66). The average selling price of all grades of domestic fluorspar shipped in 1943 ($29.07) established a new peak and was $3.58 greater than the previous high of 1919. The average selling price, f. o. b. Illinois-Kentucky mines, of metallurgical-grade fluorspar shipped to domestic steel plants was $28.69 a ton ($23.82 in 1942) and of that shipped to domestic manufacturers of hydrofluoric acid $33.86 ($28.86 in 1942).

The total quantity of fluorspar shipped in and imported into the United States from about 1870 through 1943 was approximately 6,719,000 short tons, comprising 5,615,000 tons from domestic mines and 1,104,000 tons from foreign sources. It is noteworthy that of the total domestic shipments, 1,503,372 tons (27 percent) were shipped during the past 5 years (1939–43).

POST-WAR OUTLOOK

Consumption of fluorspar for several years after the war probably will be substantially greater than during the 5 pre-war years. The steel industry will, as heretofore, continue to influence profoundly the prosperity of the domestic fluorspar industry. Although some of the conservation measures effected during the war doubtless will be continued, it is believed unlikely that the average consumption of fluorspar per ton of steel produced will drop below that of 5.4 and 5.2 pounds, respectively, in 1939 and 1940. Although the production of steel will decline substantially with the ending of the war, many authorities believe that it will be maintained at a high level for some time. Should an annual average production of, say, 50,000,000 long tons of basic open-hearth and basic electric steels be maintained during the 5 post-war years an annual consumption of 145,000 to 150,000 short tons of fluorspar probably would be required.

Establishment of important new uses and a growing demand in some of the older uses for hydrofluoric acid have resulted in a large increase in consumption of fluorspar during the war. During the 2 years 1942–43 the average consumption of fluorspar in the manufacture of hydrofluoric acid was 97,600 tons as compared with an average of 32,500 tons during the 5 years 1937–41. Although consumption will decline after the war, it is likely to be substantially greater than during the 5 years 1937–41.

It is believed that the future requirements of ceramic grades will exceed those for 1937–41, which averaged 20,000 tons, and future consumption in the production of iron castings, ferro-alloys, primary and secondary nonferrous metals, cement, and other miscellaneous operations will be maintained at least at the pre-war level and may advance somewhat.

Consequently, an average consumption of 225,000 to 250,000 tons for several years after the war appears to be possible.

PRODUCTION AND SHIPMENTS

Production of finished fluorspar totaled 405,600 short tons in 1943, including 159,758 tons of flotation concentrates. In addition, 66,000 tons of crude ore, equivalent to 27,400 tons of finished fluorspar, were mined but not milled in 1943. Thus, total production (expressed in terms of finished fluorspar) was 433,000 tons in 1943 compared with 337,000 tons in 1942. Of the quantity produced in 1943, 12 mines producing over 10,000 tons each supplied 212,000 tons or 49 percent, 12 mines producing 5,000 to 10,000 tons each supplied 80,000 tons or 18 percent, and 35 mines producing 1,000 to 5,000 tons each supplied 90,000 tons or 21 percent; thus, 59 mines produced 382,000 tons or 88 percent of the total. The remainder (51,000 tons or 12 percent) was produced in quantities ranging from a few tons to 1,000 tons from an undetermined number of small mines and prospects and reclaimed from waste dumps and old workings of abandoned mines.

Fluorspar shipments from domestic mines in 1943 were the largest on record and aggregated 406,016 short tons valued at $11,802,255, representing increases of 13 percent in quantity and 33 percent in total value over 1942. Of the 1943 total, 49,913 tons were shipped by river or river-rail for delivery to consumers as compared with 79,049 tons (an all-time high) in 1942.

Illinois (49 percent) and Kentucky (27 percent) supplied 76 percent of the fluorspar shipped in 1943 compared with 82 percent in 1942 and 86 percent in 1941. Shipments from Illinois and Kentucky in 1943 gained only 4 percent over 1942 compared with an increase of 52 percent in the West.

The average value of all grades of finished fluorspar shipped in 1943 was $29.07 a short ton ($4.38 more than the 1942 average).

The following table shows shipments of fluorspar, by States, 1942 and 1943. (For historical table, see Minerals Yearbook, 1941, p. 1401.)

Shipments of fluorspar in 1943 comprised 226,461 tons of fluxing gravel and foundry lump, 158,724 tons of flotation concentrates, 20,263 tons of ground, and 568 tons of acid lump. The bulk of the fluxing-gravel and foundry-lump fluorspar was shipped to steel plants and iron foundries, but a comparatively small tonnage moved to plants making cement, ferro-alloys, nickel, basic refractories, and fluxing compounds, to smelters of secondary metals, and to the Government stock pile. Hydrofluoric-acid plants took 77 percent of the flotation con-

centrates shipped in 1943; the remainder went to aluminum- and magnesium-reduction works, to steel, ferro-alloy, glass, enamel, and nickel plants, to smelters of secondary metals, and to the Government stock pile. Over two-thirds of the ground fluorspar was shipped to glass and enamel plants; the remainder moved chiefly to manufacturers of welding rods, magnesium, ferro-alloys, and steel and to smelters of secondary metals. Except for 20 tons to a steel plant and 1 ton to a nonferrous smelter, all the acid lump fluorspar was shipped to hydrofluoric-acid plants.

The next table shows shipments of fluorspar, by grades and industries, in 1943.

SHIPMENTS, BY USES

The steel industry is the predominant purchaser of fluorspar, as is evident from the following table; it also consumes considerable hydrofluoric acid and sodium fluoride, in which fluorspar is the basic material.

Fluorspar shipped from mines in the United States, 1942–43, by uses

Use	1942				1943

USES

As figure 1 shows graphically, the steel industry is the chief consumer of fluorspar in the United States. Fluorspar is used as a flux in basic open-hearth and basic electric steel furnaces; a comparatively small quantity is employed in Bessemer-steel furnaces. The second-largest use is in the manufacture of hydrofluoric acid, which is utilized to make artificial cryolite and aluminum fluoride (aluminum raw materials), refrigerating mediums, and insecticides; hydrofluoric acid is also used in the electrolytic refining of metals, the pickling of metals, chromium plating, the processing of high-octane gasoline, and the etching of glassware, as well as for other purposes. The glass industry, which employs fluorspar as an opacifier and as a flux, ranks third in importance. The enamel industry uses fluorspar as an ingredient in frit; it formerly ranked fourth but dropped to tenth place in 1943. Comparatively small quantities of fluorspar are used in a number of miscellaneous operations, such as production of the finer grades of iron castings, chilled-iron rolls, primary and secondary nonferrous metals, cement, ferro-alloys, carbon electrodes, rock wool, basic refractory cements, and calcium carbide and cyanamid; as a paint pigment; as a binder for abrasives; in a formula for coating welding rods; as a boiler-cleaning compound; as a flux to deslag high-pressure generators; for stripping anodizing racks; as an ingredient in various types of fluxing compounds; and in the manufacture of surfacing for roofing.

One of the most important wartime developments in aviation-gasoline manufacture is the anhydrous hydrofluoric acid alkylation process, in which hydrogen fluoride is the catalyst instead of the usual sulfuric acid. Frey[3] has described this process. Another important wartime invention is the new aerosol dispenser for protection of the Army overseas from malaria mosquitoes, which uses Freon, a nonpoisonous gas employed for refrigerating systems. Both developments resulted in greatly increased demand for acid-grade fluorspar in 1943. Considerable publicity was given to the use of sodium fluoride to retard tooth decay.

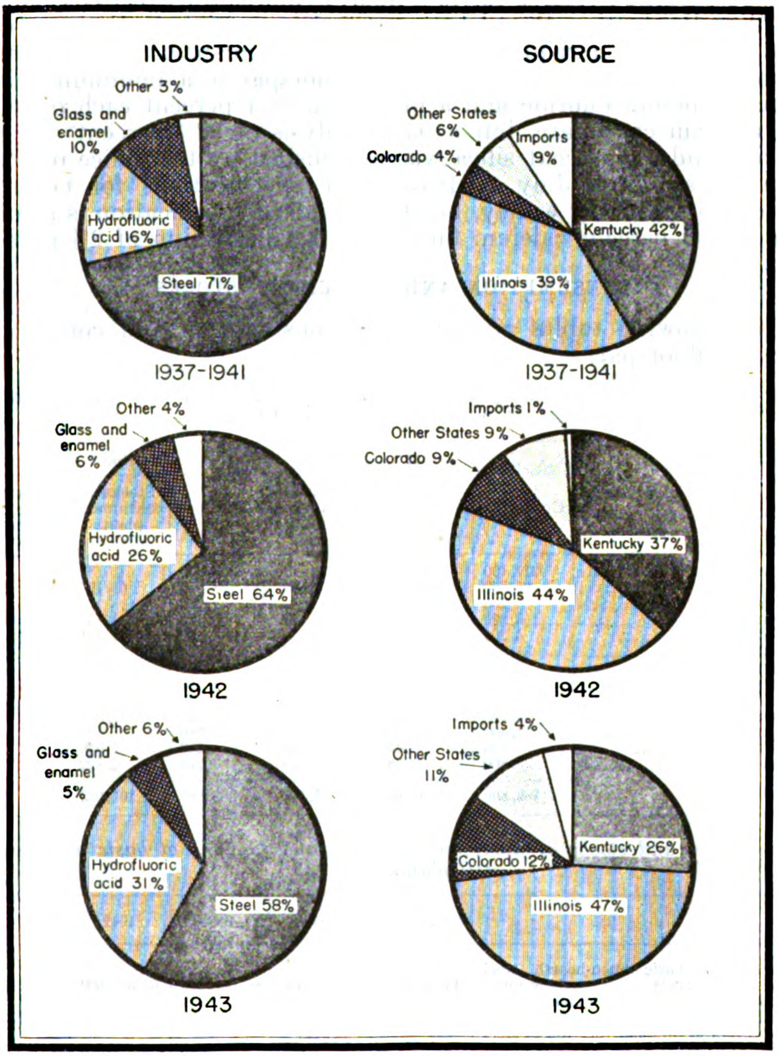

FIGURE 1.—Average annual fluorspar sales (domestic and foreign) to consumers in the United States, 1937-41, compared with 1942 and 1943, by consuming industries and by sources.

SPECIFICATIONS

The chief commercial grades of fluorspar are metallurgical, ceramic, and acid. The standard chemical specification for metallurgical grade is a minimum of 85 percent calcium fluoride and a maximum of 5 percent silica; it contains 72½ percent effective calcium fluoride. However, because of a scarcity of metallurgical-grade fluorspar in 1942, many consumers voluntarily accepted a lower-grade product.

Production of metallurgical-grade fluorspar continued to lag behind consumption during the first half of 1943, and as a consequence the Office of Price Administration, effective August 30, 1943, prohibited the sale or delivery of metallurgical-grade fluorspar containing more than 60 percent effective calcium fluoride unless the Steel Division of the War Production Board had certified in writing to the producer that the purchaser required a higher-grade fluorspar. The standard chemical specification for acid-grade fluorspar is a minimum of 98 percent calcium fluoride and a maximum of 1 percent each of silica and calcium carbonate, but a base analysis of 97½ percent calcium fluoride and 1½ percent silica was established by the Office of Price Administration on July 1, 1943. The specifications for ceramic-grade fluorspar vary widely, but the standard specification is a minimum of 95 percent calcium fluoride and a maximum of 2½ percent silica.

CONSUMPTION AND CONSUMERS' STOCKS

The following tables give data on consumption and consumers' stocks of fluorspar.

Fluorspar (domestic and foreign) consumed and in stock in the United States, 1942–43, by industries, in short tons

Industry	1942			1943		
	Consumption	Stocks at consumers' plants Dec. 31	In transit to consumers' plants Dec. 31	Consumption	Stocks at consumers' plants Dec. 31	In transit to consumers' plants Dec. 31

Miscellaneous	2,800	1,300	118	3,214	2,822	348
	360,800	96,000	5,600	388,885	105,933	5,531

Consumption and stocks of fluorspar (domestic and foreign) at basic open-hearth steel plants, 1939–43

	1939	1940	1941	1942	1943
Production of basic open-hearth steel ingots and castings……long tons	43,368,000	55,038,000	66,056,000	67,821,000	69,695,000
Consumption of fluorspar in basic open-hearth steel production……short tons	116,200	143,800	191,300	217,100	205,676
Consumption of fluorspar per ton of steel made……pounds	5.4	5.2	5.8	6.4	5.9
Stocks of fluorspar on hand at steel plants at end of year……short tons	69,900	79,800	84,200	60,400	57,200

The quantity of fluorspar used per long ton of basic open-hearth steel varies with each plant, each operator, each furnace, and each heat but probably ranges from less than 1 pound to 80 pounds. The average for all plants is generally 5 to 8 pounds—a relatively small proportion of the furnace charge. From 1921 (the first year for which these data were collected) to 1940 the average consumption of fluorspar per long ton of steel made declined almost steadily from 8.2 to 5.2 pounds; it increased to 5.8 pounds in 1941 and further to 6.4 pounds in 1942—the highest since 1935. However, it declined to 5.9 pounds in 1943. The decreased consumption in 1943 was due chiefly to conservation measures, rather than to the use of substitutes. Although basic electric steel plants are small users of fluorspar as compared with basic open-hearth steel plants, the average consumption of fluorspar (12.8 pounds in 1943) per long ton of basic electric steel made is substantially greater. However, as in basic open-hearth, the average consumption of fluorspar per ton of basic electric steel made also declined in 1943.

Fluorspar was reported consumed in 37 States and the District of Columbia in 1943, but three States—Illinois, Ohio, and Pennsylvania—used 241,683 tons or 62 percent of the total consumption. In addition to being the chief fluorspar-producing State, Illinois was also the largest consuming State in 1943, taking 87,702 tons or 23 percent of the total. Although ranking third as a consumer of fluorspar in steel, Illinois was the largest consumer of fluorspar in hydrofluoric acid in 1943. Pennsylvania, the second largest consumer in 1943, ranked first in consumption in both steel and glass.

The next table shows, so far as possible without revealing the figures of individual companies, the consumption of fluorspar by States and by consuming industries.

Fluorspar (domestic and foreign) consumed in the United States in 1943, by States and industries, in short tons

PRICES

The increased maximum prices for metallurgical-grade fluorspar, which became effective November 23, 1942, and ranged from $25 to $28 a short ton according to calcium fluoride and silica content, did not stimulate production as anticipated. Consequently, effective July 1, 1943, new base prices of $30 to $33 a ton for metallurgical-grade fluorspar were established by the Office of Price Administration in Revised Maximum Price Regulation 126 (Fluorspar), issued July 1, 1943. However, beginning August 30, 1943, the War Production Board controlled deliveries of the higher grade of metallurgical fluorspar. The new regulation also advanced the base prices of acid and ceramic grades of fluorspar to $37 a short ton.

STOCKS AT MINES OR SHIPPING POINTS

According to reports of producers, the quantity of fluorspar in stock at mines or shipping points at the close of 1943 totaled 115,937 tons or 125 percent more than in 1942. These stocks comprised 19,026 tons of finished fluorspar and 96,911 tons of crude fluorspar (calculated to be equivalent to 42,000 tons of finished fluorspar).

Stocks of fluorspar at mines or shipping points in the United States, December 31, 1942 and 1943, by States, in short tons

State	1942			1943		
	Crude[1]	Finished	Total	Crude[1]	Finished	Total
Arizona	30		30			
California	150		150	150	7	157
Colorado	3,601	1,067	4,668	39,108	892	40,000
Idaho				50		50
Illinois	10,521	13,984	24,505	34,079	6,363	40,442
Kentucky	1,774	3,970	5,744	6,541	10,498	17,039
Nevada					200	200
New Mexico	15,605	312	15,917	16,983	573	17,556
Texas					293	293
Utah	500	96	596		200	200
	32,181	19,429	51,610	96,911	19,026	115,937

[1] The greater part of this crude (run-of-mine) fluorspar must be beneficiated before it can be marketed.

TECHNOLOGIC DEVELOPMENTS

Laboratory tests of the Heavy-Media Process for the milling of fluorspar ores having proved encouraging, mills employing this process were installed in 1943 by three companies—Rosiclare Lead & Fluorspar Mining Co. at Rosiclare, Ill., Western Fluorspar Corporation at Northgate, Colo., and Metals Reserve Co. at Gila, N. Mex. The mills of the Western Fluorspar Corporation and Metals Reserve Co. began operating in December 1943. The mill of the Rosiclare Lead & Fluorspar Mining Co. began operating in March 1944, and according to A. H. Cronk, superintendent, "The results are very encouraging and are somewhat better than the laboratory results as determined by the American Cyanamid Co." A fourth company has a Heavy-Media Process mill under consideration. This method of milling is reported to be very satisfactory for free-milling ore and to be more efficient than jigging. Ferrosilicon is used for the heavy medium.

A flotation plant was completed by the Zuñi Milling Co. at Los Lunas, N. Mex., in 1943, and plants are under construction near Cave in Rock, Ill., by the Minerva Oil Co.; near Marion, Ky., by the Corod Minerals Corporation; at Albuquerque, N. Mex., by the American Fluorspar Co.; near Salida, Colo., by the Chaffee County Fluorspar Corporation; and near Forney, Idaho, by A. E. Chambers. The flotation mill of Indian Metals Co. at Lordsburg, N. Mex., which was destroyed by fire, was rebuilt during 1943. Output of flotation concentrates again gained phenomenally, totaling 159,758 short tons in 1943 compared with 106,974 tons in 1942 and 64,627 tons in 1941.

FLUORSPAR INDUSTRY IN 1943, BY STATES

Arizona.—Production in Arizona in 1943, totaling 1,328 short tons of finished fluorspar, came from mines and prospects in Greenlee, Maricopa, and Yuma Counties; most of that from Greenlee County was shipped to flotation plants at Deming and Lordsburg, N. Mex. The flotation concentrates recovered from the fluorspar, rather than the run-of-mine material, have been credited in the statistics to Arizona. The fluorspar from Yuma County was shipped to steel plants in California. The fluorspar from Maricopa County came from the Big Spar, Contact, and Good Luck mines near Wickenburg and was also shipped to steel plants.

California.—Production of fluorspar in California in 1943 was 141 short tons, of which 134 tons were shipped to steel plants. It was produced at the Red Bluff mine near Midland, Riverside County, by E. T. Hermann.

Some Nevada fluorspar was ground at the plant of the Industrial Minerals & Chemical Co. at West Berkeley and shipped to nonferrous smelters and magnesium-reduction plants in 1943. The ground fluorspar is credited in the statistics to Nevada.

Colorado.—Greatly accelerated production at mines in Boulder and Chaffee Counties is indicated by the shipment of 49,145 short tons of fluorspar from Colorado in 1943 compared with 31,743 tons in 1942. Shipments in 1943 established a new record for Colorado and exceeded the previous record made in 1918 by 28 percent; they comprised 22,778 tons of fluxing gravel and foundry lump fluorspar, 25,946 tons of flotation concentrates, and 421 tons of ground fluorspar. Seventy-seven percent went to steel and hydrofluoric-acid plants but some to iron foundries and nonferrous smelters and to glass, enamel, ferro-alloy, cement, and magnesium-reduction plants. A small tonnage of fluxing gravel was shipped to the Government stock pile at Chicago.

Production of finished fluorspar in Colorado totaled 49,000 tons in 1943. In addition, 35,500 tons of crude ore, equivalent to 11,500 tons of finished fluorspar, were mined but not milled in 1943. Thus, total production (expressed in terms of finished fluorspar) was 60,500 tons in 1943. Output came from Boulder, Chaffee, Jackson, Jefferson, Mineral, and Park Counties, but mines in Boulder, Chaffee, and Jackson Counties supplied 90 percent of the State total.

During 1943 Harry M. Williamson & Son added jigs and tables to their flotation mill in Boulder County to make possible the production of both fluxing gravel and flotation concentrates. Production of finished fluorspar was about 5 percent less than in 1942 and comprised 51 percent fluxing gravel and 49 percent acid-grade flotation concentrates. The ore treated in the mill came from the company-operated Argo, Brown Spar, and Emmett mines in Boulder County. Some milling ore was sold to the nearby flotation mill of the General Chemical Co. The shaft at the Emmett mine was sunk an additional 200 feet to a depth of 475 feet. At the Argo shaft a new hoist house, a head frame, and an ore bin were erected, a drift was driven on the winze level to a point under the shaft, and a raise was driven to the bottom of the old shaft.

Production of flotation concentrates at the mill (near Jamestown) of General Chemical Co. about tripled that in 1942. The output of the mill was shipped to the hydrofluoric-acid plants of the company. The flotation-mill feed comprised ore from the company-operated Alice, Burlington, Chancellor, and Yellow Girl mines in Boulder County and some purchased ore. This company also operates a flotation mill in New Mexico.

The Colorado Fluorspar Corporation, which operates a combination flotation-jig mill and a mine near Salida, Chaffee County, produced about 67 percent more finished fluorspar than in 1942. Production in 1943 comprised 61 percent fluxing gravel and foundry lump and 39 percent flotation concentrates. Development consisted of about 1,200 feet of drifting, which resulted in opening additional ore reserves.

During 1943 the Chaffee County Fluorspar Corporation, with a property near Salida, produced and sold some crude ore to a local mill, did considerable development, and in the fall began to construct a flotation mill.

The flotation mill of Kramer Mines, Inc., near Salida, which started operating in October 1942, made a substantial output of concentrates in 1943. The mill feed comprised chiefly ore from the company mines near Salida and Poncha Springs, Chaffee County, and Northgate, Jackson County; some purchased ore mainly from the Chaffee County was also milled. The company did considerable development at its claims in Jackson County. Fleming[4] has described the Chaffee County mines and mill of the Kramer Mines, Inc.

The Western Feldspar Milling Co., Denver, ground 421 short tons of fluorspar, which was shipped to glass plants in 1943. The ore was supplied by the American Fluorspar Corporation. The Western Feldspar Milling Co. discontinued grinding fluorspar in July 1943.

The American Fluorspar Corporation, operating mines near Salida and Poncha Springs (Chaffee County), produced 9 percent more finished fluorspar than in 1942, but its output of milling ore almost tripled the 1942 figure. The flotation mill of the Fluorspar Processing Co.—on property of the American Fluorspar Corporation, which supplies its milling ore—produced 103 percent more fluorspar concentrates than in 1942. Reconditioned flotation cells, a drier, and pumps were installed in the mill, and new loading bins and an elevator to loading bins were constructed. Other improvements included concrete floors throughout the mill and a boiler to provide hot water.

The Western Fluorspar Corporation mill near Northgate, Jackson County, which was destroyed by fire on December 10, 1942, was rebuilt during 1943 and began operating in December. The mill uses the Heavy-Media Process for separating fluorspar from gangue material, with ferrosilicon as the heavy medium. During the building of the mill the company mined a substantial tonnage of ore, some of which was hand-sorted and shipped.

---

[4] Fleming, Roscoe, Fluorspar Helps Wage War: Compressed Air Mag., vol. 48, No. 10, October 1943, pp. 7160-7163.

The Wagon Wheel Gap mine of the Colorado Fuel & Iron Corporation was operated 10 months in 1943 as compared with 11 months in 1942; production therefore declined slightly.

Small quantities of fluorspar, which were shipped to steel mills, were produced at the Augusta mine in Jefferson County and the Lake George and Bear Cat mines in Park County.

Idaho.—The Chamac mine near Forney, Lemhi County, was being developed during 1943 by A. E. Chambers, who since October has been constructing a 70-ton flotation mill.

Anderson [5] has described the fluorspar deposits near Meyers Cove, Lemhi County.

Illinois.—Production of finished fluorspar in Illinois was 191,000 short tons in 1943; about 94 percent came from Hardin County and 6 percent from Pope County. In addition, 24,000 tons of crude ore, equivalent to about 13,000 tons of finished fluorspar, were mined but not milled. Thus, total production in 1943 (expressed in terms of finished fluorspar) was 204,000 tons. Considerable Kentucky fluorspar is milled in Illinois, and some Illinois fluorspar is milled in Kentucky; the finished fluorspar so recovered, as well as that shipped, is credited in the statistics to the State of origin. The Argo, Austin, Blue Diggings, Crystal, Daisy-North Daisy, A. L. Davis, Deardorff, Dimick, Douglas, Fairview, Good Hope, West Green, Hillside, Lead Hill, Midway-North Boundary-Air Shaft, Roberts, Rosiclare, Stewart, and Victory properties supplied about 85 percent of the fluorspar produced in Illinois in 1943; the remainder came from many mines and prospects, including the Cave in Rock, Eureka No. 4 and No. 5, East Green, Hawkins Shaft, J. W. Hill, Last Chance, Lost 40, Rock Candy Mountain, Rose Creek, South Boundary-Deep Shaft, and Wall.

Shipments of fluorspar from Illinois (198,789 tons) constituted 49 percent of the total shipped in 1943 and established a new record—23 percent greater than in 1942, the previous record year. The 1943 shipments comprised 89,789 tons to steel plants, 89,599 tons to hydrofluoric-acid plants, 6,741 tons to glass and enamel plants, 2,333 tons to Algeria, Canada, and Peru, and 10,327 tons to iron foundries, nonferrous smelters, aluminum- and magnesium-reduction plants, and ferro-alloy, nickel, and welding-rod manufacturers. Of the 1943 total, 36,643 tons were shipped by river or river-rail to consumers compared with 42,250 tons in 1942.

The Fluorspar Products Co. operated the Lead Hill and Stewart mines and milled purchased ore from various properties. Shipments were 38 percent more than in 1942.

The Aluminum Ore Co., the largest producer of fluorspar in the United States in 1943, produced 58 percent more fluorspar at its flotation plant than in 1942. The mill feed comprised ore from the company-operated Argo, Blue Diggings, Fairview, Good Hope, Hamp and Last Chance mines and some purchased ore, chiefly from the Rose Creek and Rock Candy Mountain mines. The new 700-foot shaft at the Fairview mine, on the Argo-Blue Diggings veins, was completed and put into operation in June 1943. Underground development was carried forward on the Argo vein on various levels operating through the Blue Diggings shaft. Development was continued on the various levels from the Blue Diggings and the Fairview shafts. Additional boiler and generating capacity was installed to take care of the electrically operated Fairview mine.

---

[5] Anderson, A. L., The Antimony and Fluorspar Deposits near Meyers Cove, Lemhi County, Idaho. Idaho Bureau of Mines and Geol., Pamph. 62, March 1943, 22 pp.

In 1943, as in 1942, considerable output was lost at the Crystal mine of the Crystal Fluorspar Co. because of two strikes. Production was about the same in both years. An unknown ore body below the creek bed was found by drilling, and a shaft was being sunk on this ore body. The company did 20,500 feet of churn and diamond drilling in 1943.

Production of gravel fluorspar and flotation concentrates by Hillside Fluor Spar Mines was 12 and 15 percent, respectively, less than in 1942. The mill feed comprised ore from the Dimick, Hillside, and Wall mines at Rosiclare, Ill., the Keystone mine near Marion, Ky., and tailings from previous milling operations. Production and shipments of finished fluorspar from the Keystone mine have been credited in the statistics to Kentucky. The Hillside Fluor Spar Mines were acquired on June 1, 1943, by the Inland Steel Co., which will operate the property as a separate unit and continue to serve other consumers.

The Victory mine of the Victory Fluorspar Mining Co. produced 14 percent less fluorspar than in 1942.

Most of the output from the mine of the General Finance Corporation was sold to local mills. However, some of the ore was milled by the company, and the fluxing-gravel fluorspar produced was shipped to steel plants.

The flotation mill of the Mahoning Mining Co. produced 12 percent more fluorspar concentrates than in 1942. The mill feed comprised ore from the A. L. Davis, Deardorff, East Green, and West Green mines and some purchased ore. Production of finished fluorspar comprised 76.5 percent acid-grade and 23.5 percent pelletized gravel. Shaft sinking and underground development were completed at the East Green mine, which began producing in 1943. The flotation-mill expansion program was completed during 1943.

James W. Patton & Sons again treated tailings from the Crystal mine in its flotation mill and also treated some tailings from the C. R. Babb mine for Roberts & Frazer.

The Yingling Mining Co. operated the Rose Creek mine, and the output was sold to a local mill for treatment; however, the company also purchased and milled ore from the Douglas mine, which it acquired in December.

The Minerva Oil Co. continued development at its mine near Cave in Rock and was constructing a flotation mill near the mine. Both units were expected to get into production during March 1944.

The Rosiclare Lead & Fluorspar Mining Co. operated the Daisy-North Daisy, Eureka No. 4 and No. 5, Hawkins Shaft, Midway-North Boundary-Air Shaft, Rosiclare, and South Boundary-Deep Shaft in 1943, but the Rosiclare mine was the chief producer. Production at the gravity-concentration mill and flotation mill was 21 and 8 percent greater than in 1942. Shipments of fluorspar of all grades were 22 percent greater than in 1942. A Heavy-Media Process mill for separating fluorspar from gangue material was nearing completion at the close of 1943. The separating cone is 14 feet in diameter, and ferrosilicon is to be used for the heavy medium. The ore treated will be plus 10-mesh to 1 inch. The minus 10-mesh ore will be flotation-mill feed. The Heavy-Media mill will eliminate the use of jigs. Three diamond drills were operated to find additional ore bodies and new veins; some of the results were satisfactory. The Hawkins, a new mine about 1 mile north of the Rosiclare vein, was opened, and mining in good ore was in progress at the 100-foot level. A submersible pump having a capacity of 1,800 gallons a minute at 650-foot head and equipped with a 350-horsepower motor was installed in the Rosiclare mine in 1943 for pumping protection. This gives a pumping capacity of 8,800 gallons a minute, or about double the inflow of water. A 500-kilowatt turbine generator was added to the power plant.

Production at the Roberts mine in Pope County, operated by Roberts & Frazer of Illinois (Kentucky Fluor Spar Co. affiliate), was substantially greater than in 1942. The known ore in this mine was exhausted in November 1943.

The Rock Candy Mountain mine, also in Pope County, operated by the Big Creek Mining Co., produced considerable crude ore, which was sold to local mills.

Kentucky.—Production of finished fluorspar in Kentucky was 116,500 short tons in 1943. In addition, 5,000 tons of crude ore, equivalent to 2,500 tons of finished fluorspar, were mined but not milled. Thus, production (expressed in terms of finished fluorspar) totaled 119,000 tons in 1943. Shipments again declined and amounted to 109,849 tons—a decrease of 18 percent from 1942 and 23 percent less than the all-time record for 1941. The 1943 shipments comprised 89,419 tons to steel plants, 10,153 tons to glass and enamel plants, 1,739 tons to hydrofluoric-acid plants, 1,889 tons to Canada, and 6,649 tons to iron foundries, nonferrous smelters, and cement, ferro-alloy, aluminum-reduction, and miscellaneous plants. Of the 1943 total, 15,270 tons were shipped to consumers by river or river-rail compared with 36,799 tons in 1942.

Output in Caldwell County came chiefly from the Crook, Glass, Hollowell & Hobby, Hughett, Perkins, and Senator mines, most of it being from the Hollowell & Hobby, Hughett, and Senator mines.

Output at the mine of Hughett Mining Co. near Princeton about doubled that of 1942.

The New York & Kentucky Mining Co., operating the Hollowell & Hobby mine near Princeton, produced 12 percent more fluorspar than in 1942.

The Midland Minerals Corporation, which was organized late in 1942, commenced operations at the Senator mine near Princeton in January 1943 and produced a substantial tonnage of fluxing-gravel fluorspar during the year.

The major part of the output in Crittenden County came from a few mines—Bachelor, Davenport, Keystone, Pigmy, Tabb, and Watson (Eagle). Most of the remainder came from many smaller mines (including the Babb, Barnes, Blue, Columbia, Gilless, Guill, Hodge, Krause, La Rue, Marion Lake, Summers, and Watkins) and from numerous prospects; some was reclaimed from waste dumps and old workings of abandoned mines.

The Eagle Fluorspar Co. worked the Adams, Babb, Guill, and Watson (Eagle) mines and produced 33 percent less finished fluorspar than in 1942. The Babb mine was under development in 1943. Perry and Loyd reworked the Watson tailings and recovered considerable fluorspar.

Operations at the Summers mine and mill of R. J. Forester were suspended in July 1943; consequently, production was substantially less than in 1942.

The Tabb mines and mill of the United States Coal & Coke Co. produced 14 percent less finished fluorspar than in 1942, but shipments declined 47 percent. The company did considerable development in 1943.

The Kentucky Fluor Spar Co. and affiliates did the largest volume of business in its history; tonnage and dollar sales were 8 and 16 percent, respectively, greater than in 1942, the previous record year. The company operates a mill near Marion, and through its mining divisions (Roberts & Frazer and Hettiger & Frazer), operated the C. R. Babb, Carr, Ellis, and Wright mines in Livingston County, the Pepper Box mine in Crittenden County, and the Roberts mine in Pope County, Ill., in 1943. About three-fourths of the company supply came from these mines, and the remainder chiefly from the Barnes, Blue, Hollowell & Hobby, and Nancy Hanks.

Production at the Keystone mine of Hillside Fluor Spar Mines was substantially less than in 1942. Although the fluorspar from this mine is finished at the company mill at Rosiclare, Ill., production and shipments are credited in the statistics to Kentucky.

At the Pigmy mine of the Pigmy Corporation (subsidiary of the Rosiclare Lead & Fluorspar Mining Co.) production was 11 percent less than in 1942. A newly located ore body was developed further by extension of the 100-foot level, and the results were very encouraging. A diamond drill was operated on the Pigmy property during 1943, and the results indicated further downward extension of the ore body on the west side of the property.

During 1943 the National Fluorspar Co. sank a 300-foot shaft on a newly discovered ore body in its Davenport mine. A new 7-inch Pomona pump and a 66-horsepower Diesel engine will be installed in 1944. The power plant was being moved to the new location. The lower working levels of the old shaft were flooded from March to July; meanwhile, production was confined to a small tonnage of low-grade ore from the upper levels and to the re-treatment of about 1,000 tons of tailings. Consequently, production of finished fluorspar was 22 percent less than in 1942.

Output at the Bachelor mine of the Delhi Fluorspar Corporation was at a greatly reduced rate in 1943. However, the company purchased both finished fluorspar and milling ore from many producers, and consequently its shipments were much greater than in 1942.

Shipments of fluorspar by L. Conyer, operating a mill near Marion, were two and one-half times those of 1942. Conyer does not operate any mines but purchases milling ore from various mines. The bulk of the ore milled in 1943 was supplied by the Hughett Mining Co. and Craighead Bros.

The Corod Minerals Corporation was constructing a flotation mill near Marion in 1943. It mined a small quantity of ore at the Columbia mine.

In Livingston County most of the fluorspar output came from the C. R. Babb, Carr, Junior, Nancy Hanks, and Wright mines, from

C. R. Babb and Nancy Hanks tailings, and from the reclaiming plant working Klondike tailings.

Output at the C. R. Babb, Carr, Ellis, and Wright mines of Roberts & Frazer was slightly greater than in 1942. E. W. Frazer reworked the tailings at the C. R. Babb mine and recovered 1,130 tons of fluorspar. Some tailings from the C. R. Babb mine were treated at the Patton flotation mill in Illinois and 186 tons of acid-grade concentrates were recovered.

Production at the Nancy Hanks mine, operated by W. V. Haynes, Jr., was retarded somewhat because of development during 1943, and output of finished fluorspar was slightly less than in 1942. Tinsley & Loyd reclaimed a substantial tonnage of fluorspar from Nancy Hanks tailings.

Butler & Moodie, operating the Junior mine and reclaiming fluorspar from the Klondike-mine tailings, recovered 29 percent more fluorspar than in 1942.

In the Central Kentucky district production of fluorspar increased to 2,469 short tons in 1943 (79 tons in 1942). Output in this district came from the Faircloth mine in Woodford County, near Wilmore, operated by Ralph E. Jones; the Lone Oak mine near Harrodsburg in Mercer County, operated by the Lone Oak Ore Co.; and a property near Talmage, also in Mercer County, operated by Mercer Minerals, Inc. The Twin Chimney mine near Mundys Landing in Mercer County was acquired by the Lone Oak Ore Co. and began producing fluorspar in January 1944. The Faircloth mine was equipped with an electrically operated hoist and a pump in 1943. A new ore body was found one-fourth mile from the Faircloth mine. The shaft at the mine of Mercer Minerals, Inc., was sunk 125 feet.

Nevada.—Shipments of fluorspar from Nevada in 1943 (8,653 short tons) were 8 percent greater than in 1942 but 4 percent under the all-time record of 1941. Most of the 1943 total went to steel plants, but some was shipped to hydrofluoric-acid, ferro-alloy, and cement plants and to nonferrous smelters.

The chief producing mine in Nevada in 1943 was the Baxter in Mineral County, operated by V. S. Baxter. Production was 10 percent more than in 1942. The other chief producing mine was the Daisy in Nye County, operated by J. Irving Crowell, Jr.; production was also 10 percent greater than in 1942. A carload of fluorspar was produced and shipped from the Cirac mine in Churchill County, operated by E. S. Perry and associates.

New Mexico.—Production of finished fluorspar in New Mexico totaled 37,300 short tons in 1943. In addition, 1,400 tons of crude ore, equivalent to 400 tons of finished fluorspar, were mined but not milled in 1943. Thus, total production (expressed in terms of finished fluorspar) was 37,700 tons in 1943. The output came chiefly from Grant, Luna, Sierra, and Valencia Counties.

Shipments from New Mexico totaled 37,050 short tons, a gain of 64 percent over the all-time high of 1942. Most of the 1943 shipments were flotation concentrates, which moved chiefly to hydrofluoric-acid plants, but some was shipped to steel, glass, enamel, ferro-alloy, and magnesium-reduction plants and to the Government stock pile at East St. Louis, Ill. Most of the metallurgical-grade fluorspar went to steel plants and iron foundries, but some was shipped to the Government stock pile at Chicago.

The flotation mill of the General Chemical Co. at Deming was operated at about the same rate as in 1942. The mill feed comprised ore from the company Spar Group and Sadler mines in Luna County and the Osmer mine in Grant County, and considerable purchased ore from local mines. Virtually all the flotation concentrates produced were shipped to the hydrofluoric-acid plants of the company.

The flotation plant of the Zuñi Milling Co. at Los Lunas made its initial production in March 1943 and was the largest producer of fluorspar in New Mexico in 1943. Most of the concentrates were shipped to hydrofluoric-acid plants, but some were shipped to the Government stock pile at East St. Louis, Ill., and to glass plants. The mill feed is supplied by the Navajo mine in Valencia County. In addition to supplying milling ore to the flotation plant, the Navajo mine shipped 7,700 tons of fluxing-gravel fluorspar. The Navajo mine was acquired during the latter part of 1943 by the Shattuck Denn Mining Corporation, which has also taken over management of the flotation plant at Los Lunas.

The flotation mill of the Indian Metals Co. at Lordsburg was destroyed by fire on March 28, 1943; it was rebuilt and began operating again in July. Consequently, production was substantially less than in 1942. The mill feed is supplied by various mines and prospects in Arizona and New Mexico. The 1943 shipments went to steel, hydrofluoric-acid, and magnesium-reduction plants.

Production of flotation concentrates at the mill of P. L. Grattan at Deming was 66 percent greater than in 1942. The mill feed was supplied by the company mine and by purchased ore. The 1943 shipments moved to hydrofluoric-acid, steel, enamel, and magnesium-reduction plants.

J. K. Stanland continued development at the Blue Diamond mine in Dona Ana County, in the course of which some milling ore was produced and shipped to a local flotation plant. The gravity-concentration mill under construction was not completed in 1943.

A mill for producing fluxing-gravel fluorspar was completed and put into operation at Gila on December 27, 1943. The mill is owned by the Metals Reserve Co. and will be operated for it by the International Minerals & Chemical Co. to mill ore purchased from surrounding mines. Concentration is by the Heavy-Media Process, using ferrosilicon as the heavy medium. Pending completion of the mill a substantial tonnage of ore was accumulated at the mill; most of it was supplied by Brown & Johnson Corporation, chiefly from the Clum mine near Gila, and by McCray & Penn from the Burro Chief mine near Tyrone.

The Lyda K mine in Sierra County, owned by Kinetic Chemicals, Inc. (du Pont subsidiary), was put in operation in the early part of 1943 to produce a small quantity of metallurgical fluorspar and at the same time to carry on further exploration and development. The ore was found to be difficult to convert to metallurgical grade by simple hand sorting; after 201 tons were produced and shipped, production was discontinued, but development was continued the remainder of the year. The middle or No. 2 shaft was being deepened to explore on the 220-foot level a section of the ground that had not been explored earlier when diamond drilling was conducted in the south half of the ore body. Deepening of the shaft was expected to be completed in early 1944, after which drifting along the vein will be conducted.

In June 1943 J. K. Stanland acquired the Bonita mine, where he did considerable development, in the course of which some ore was taken out and milled at the plant of Both Mining & Milling Co. This mine was acquired on December 9 by the Bonita Trust, which continued development and produced a small quantity of metallurgical-grade fluorspar.

During the first half of 1943 Both Mining & Milling Co. produced a small tonnage of fluxing-gravel fluorspar at the Bonita mine in Valencia County. The company did custom milling for others at its concentrating plant at Grants.

Development was in progress during 1943 at the Blackbird prospect near Albuquerque in Bernalillo County by the American Fluorspar Co. A jig mill was constructed but proved unsatisfactory. Subsequently, a flotation mill was purchased and was being installed at Albuquerque. It was expected to be completed in March 1944.

Tennessee.—A small quantity of ore mined at a property presumably in Smith County near Rome was trucked to Marion, Ky., where it was finished in the mill of Delhi Fluorspar Corporation.

Texas.—Previous commercial production of fluorspar in Texas has consisted of small amounts of milling ore, which were shipped to a flotation plant at Deming, N. Mex. In 1943, however, production amounted to 1,253 tons, of which 960 tons were shipped to steel plants. Production came from the Glass & O'Brien mine in Burnet County and the Eagle Springs, Fenley, and Eagle Mountains mines in Hudspeth County. Operations at the Glass & O'Brien and Eagle Springs mines were discontinued during 1943. At the Eagle Mountains mine, operated by the Texas Fluorite Co., a concentrating mill was under construction. The fluorspar deposits of Hudspeth County have been described by Evans[6] and those of Burnet County by Barnes.[7]

Utah.—Only 1 car (51 tons) of fluorspar was shipped from Utah in 1943 compared with 1,018 tons (an all-time high) in 1942. It was shipped by the Western Fluorite Co., which also did development at its properties in Beaver County. Fred Staats, operating the Staats mine, also in Beaver County, produced a small quantity of fluorspar in 1943 but made no shipments. The Tintic Standard Mining Co. continued development work at the Cougar mine near Milford in Beaver County, where a concentrating mill was nearing completion at the end of 1943.

FOREIGN TRADE

Imports.—Imports of fluorspar for consumption in the United States in 1943 were the largest since 1930 and reached 43,570 short tons (1,854 tons containing more than 97 percent calcium fluoride and 41,716 tons containing not more than 97 percent calcium fluoride), valued[8] at $643,409, compared with 2,151 tons (1,882 tons containing more than and 269 tons containing less than 97 percent calcium fluoride), valued[8] at $35,529 in 1942. The value assigned to the higher-grade foreign fluorspar averaged $16.98 and $22.46, respectively, in 1942 and 1943, and that of the lower-grade $13.30 and $14.43, respectively. The cost to consumers in the United States also includes duty, loading charges, insurance, consular fee, and freight to consuming plants. The duty on fluorspar containing not more than 97 percent calcium fluoride is $5.625 a short ton and on fluorspar containing more than 97 percent calcium fluoride, $3.75 a short ton.

[1] For historical table, see Minerals Yearbook, 1941, p. 1401.

The following table, compiled from data furnished to the Bureau of Mines by importers, shows the quantities of imported fluorspar delivered to consumers in the United States in 1942 and 1943, irrespective of the year of importation into the United States; it differs from the preceding table, which shows the quantities received in the United States during 1942 and 1943. The quantities in the following table are based upon the actual outturn weights ascertained by sworn weighers and represent the weights on which duty was paid and entries were liquidated.

Imported fluorspar delivered to consumers in the United States, 1942–43, by uses

[1] Estimated.

Exports.—Producers of fluorspar reported exports of 9,044 short tons of fluorspar valued at $246,973 in 1943 compared with 9,016 tons valued at $242,545 in 1942. The exports by producers in 1943 comprised 1,936 tons of fluxing gravel, 435 tons of ceramic ground, and 6,364 tons of flotation concentrates to Canada, 9 tons of fluxing gravel to Algeria, and 300 tons of flotation concentrates to Peru. In addition to the fluorspar exported by producers in 1943, brokers exported 24 tons—5 to Brazil, 16 to Chile, 1 each to Colombia and Uruguay, and the remainder to Argentina, Cuba, El Salvador, and Mexico.

Fluorspar reported by producers as exported from the United States, 1939-43

Year	Short tons	Value		Year	Short tons	Value

1941	12,184	277,782	22.80				

WORLD PRODUCTION

The following table shows world production of fluorspar by countries from 1937 to 1943, insofar as statistics are available. Because of restriction on the publication of statistics by the governments of many countries, few figures are available since 1939.

World production of fluorspar, 1937-43, by countries, in metric tons [1]

[1] In addition to countries listed China produces fluorspar, but data of output are not available.

[2] Data not available.

[3] Estimate.

[4] Exports.

[5] January to September, inclusive.

[6] Estimate included in total.

[7] January to June, inclusive.

Canada.—According to the Dominion Bureau of Mines, production of fluorspar in Canada has been small and intermittent, the total output from 1905 through 1942 being approximately 65,000 short tons, about half of which came from Ontario and the remainder from British Columbia. Although production increased to 12,087 short tons in 1943 (6,199 tons in 1942), output falls far short of consumption and the greater part of the requirements is met by importations from Mexico, Newfoundland, and the United States. Imports were 77,436 tons in 1943 (47,783 tons in 1942). Most of the Canadian output in 1942 and 1943 came from the Madoc area in Ontario, but a little was mined in Nova Scotia. The Dominion Government has furnished financial and other assistance in developing fluorspar deposits and has also set prices for the various grades produced.

Mexico.—Production of fluorspar in Mexico was about 17,300 short tons in 1943 compared with 3,300 tons in 1942. Exports were 24,547 tons in 1943 compared with 5,914 tons in 1942. The Azul mine near Taxco, Guerrero, supplied about 70 percent of the total output in 1943.

Newfoundland.—Production of fluorspar in Newfoundland in 1943 was more than double that of 1942. The fluorspar is produced by the St. Lawrence Corporation of Newfoundland, Ltd., and Newfoundland Fluorspar, Ltd., the latter a subsidiary of the Aluminum Co. of Canada, Ltd. The output of the St. Lawrence Corporation of Newfoundland, Ltd., is shipped to Canada and the United States; and that of Newfoundland Fluorspar, Ltd., is shipped to Arvida, Canada, where the Aluminum Co. of Canada, Ltd., has a flotation plant to mill the ore to acid grade.

The fluorspar deposits of Newfoundland have been described by Van Alstine.[9]

South Africa.—Fluorspar has become increasingly important in South Africa during recent years because of the growth of the steel industry. The fluorspar occurrences in the Union of South Africa and South-West Africa have been described recently.[10]

CRYOLITE

Imports of cryolite were 46,400 long tons valued at $3,117,888 in 1943 compared with 64,565 long tons valued at $3,859,875 in 1942. The cryolite imported in both years came from Greenland.

Cryolite occurs in commercial quantity and is mined at only one place—Ivigtut, Greenland. Gibbs[11] has described the mine at Ivigtut, grades of ore produced, methods of processing and purification, and various uses of cryolite.

Artificial cryolite was manufactured in the United States in 1943 by the Aluminum Ore Co., at East St. Louis, Ill. Production was 27 percent greater in 1943 than in 1942. Plants for the manufacture of artificial cryolite were completed at Bauxite, Ark., by the Aluminum Ore Co., and at Cornwells Heights, Pa., by the Pennsylvania Salt Manufacturing Co., but were not operated in 1943.

The chief use of cryolite is as a flux in the reduction of aluminum; comparatively small amounts are used in glass, enamels, abrasives, and insecticides.

A sizable proportion of the cryolite used in the United States is made from fluorspar. According to Frary:[12]

> The fluorspar is treated with sulfuric acid to produce hydrofluoric acid, and this is neutralized with the proper amounts of soda ash and aluminum hydrate to produce the cryolite, which is a double fluoride of sodium and aluminum (Na_3AlF_6). The artificial cryolite is quite satisfactory and, in fact, considerably lower in objectionable impurities than the natural cryolite usually used. There would be no serious difficulty in getting along with the artificial product if the supply of natural cryolite from Greenland is shut off.

SUMMARY

In spite of severe competition, continued curtailment of pottery and enamel manufacture, and scarcity of labor, sales of domestic crude feldspar in 1943 dropped less than 3 percent in quantity below the 1942 figure but rose 6 percent in value over 1942. Total realization for crude spar was the highest on record—2 percent more than in 1926, the former high year. Sales of ground feldspar advanced 2 percent in quantity and value from 1942; the 1943 tonnage was the second-highest on record, surpassed only by 1941. This active rate of production, however, was maintained only by seriously depleting stocks of crude spar, normally held in reserve, as well as processing currently mined material.

Salient statistics of the feldspar industry in the United States, 1941–43

[1] Revised figures.

A significant factor in the current activity of the feldspar industry was the increased demand for glass, particularly glass containers, undoubtedly the most important market for feldspar. Production and shipments of glass containers in 1943 increased 17 and 19 percent, respectively, over 1942 figures, while inventories dropped 43 percent during the year. Production of plate glass showed a 20-percent recovery in 1943 compared with 1942. The demand for vitrified porcelain, in the production of which substantial percentages of feldspar are used, was heavy during 1943.

---

[1] Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the United States Department of Commerce.

POST-WAR PROSPECTS

The outlook for feldspar seems rather favorable notwithstanding competing products, such as "aplite" and nepheline syenite. Present shortages of labor, however, due to higher job priorities in other industries and losses of manpower to the armed services, may result in lowered output, at least temporarily. The employment of glass for structural and other purposes and its use in many applications in place of steel, lead, rubber, tin, copper, brass, and plastics may establish permanent markets. To a certain extent, porcelain, another large consumer of feldspar, is now replacing steel, chrome, and other metals. After the war, there probably will be a heavy demand for enameled products, including refrigerators, stoves, other kitchen equipment, and similar articles, the production of which at present is curtailed.

Another favorable factor is the recovery of feldspar by froth flotation. This process has been developed for separation of quartz and feldspar, with encouraging results. Two plants whose primary product is spodumene also have been recovering feldspar by this method, and another plant now is being erected to process feldspar-rich pegmatite. These developments may presage less selective mining methods and more economical recovery of feldspar.

DOMESTIC PRODUCTION

Following the usual practice in the industry, crude feldspar is reported in long tons of 2,240 pounds and ground feldspar in short (net) tons of 2,000 pounds.

Crude feldspar.—Sales of crude feldspar in 1943 showed a decrease of 3 percent in quantity and an increase of 6 percent in value compared with 1942. The total value reported in 1943 established a new record, breaking the former high in 1926 by 2 percent.

Crude feldspar sold or used by producers in the United States, 1939–43

[1] Included under "Undistributed."
[2] Revised figures.
[3] Includes States indicated by "(1)."

States producing crude feldspar in 1943 were the same as in 1942. North Carolina produced more feldspar than in any other year in its history; production was 9 percent greater than during the previous record year 1929 and 20 percent higher than in 1942. South Dakota also established a new high in 1943, a 9-percent increase over 1942, the former high year. Output for Wyoming also increased. All other States, both those for which figures can be shown and those for which production may not be published, showed moderate to large percentage decreases. Higher costs and difficulties in procuring and keeping efficient labor, due largely to increased wages in high-priority industries and the demands of selective service, were among the most pressing troubles besetting the feldspar industry in 1943.

The average sales realization per long ton for crude feldspar increased from $4.89 in 1942 to $5.34 in 1943, or 9 percent, the highest realization reported since 1934. All States for which figures can be published except Connecticut show higher average values in 1943 than in 1942. Averages per ton for certain States in both years (1942 in parentheses) follow: North Carolina, $5.85 ($5.70); Virginia, $5.98 ($5.77); Maine, $6.17 ($6.02); Colorado, $4.29 ($4.03).

Ground feldspar.—Sales of ground feldspar by merchant mills in 1943 increased about 2 percent in both quantity and value compared with 1942 and were only 5 percent in quantity under the record year 1941. Tennessee and North Carolina mills combined supplied 30 percent of the total ground spar sold compared with 26 percent in 1942 and 27 percent in 1941 and 1940. As output in South Dakota in 1943 may not be published, the Colorado-South Dakota and North Carolina-Tennessee totals cannot be compared. In 1942, however, the Colorado-South Dakota total was 37 percent of the national total and in 1941, 34 percent. Sales of feldspar of Canadian origin ground in United

States mills totaled only 2 percent of the total merchant sales in 1943, compared with 3 percent in 1942 and 6 percent in 1937. In addition to the tonnage of Canadian origin given in the following table, some feldspar generally is imported direct by consumers, principally cleanser and pottery manufacturers.

Ground feldspar sold by merchant mills [1] in the United States, 1939–43

Year	Active mills	Domestic			Canadian			Total

[1] Excludes potters or others who grind for consumption in their own plants.

South Dakota in 1943 again ranked first in production of ground feldspar, followed by Tennessee, North Carolina, Colorado, and New Hampshire. Of the States for which figures may be shown, North Carolina-Tennessee reported a 16-percent increase, whereas both Colorado and New Jersey (which includes some spar ground in Connecticut) produced less in 1943. Sales of ground spar in New Hampshire, South Dakota, and Virginia, for which data may not be published, were larger than in 1942. Sales in 1943 in all other States declined.

[4] Includes items indicated by "(2)."

The average realization per ton for ground feldspar dropped from $10.75 in 1942 to $10.70 in 1943 but it compares favorably with the $10.67 registered in 1941 and $10.73 in 1940. The lower average value in 1943 probably was due in part to larger shipments of glass spar at the expense of the more finely ground pottery and enamel grades. For all States except New Hampshire, New Jersey, and North Carolina, however, the average value of ground spar sold was higher in 1943 than in 1942. The rate of increase in most States was moderate, ranging from 1 percent in New York to about 9 percent in South Dakota. Average values for individual States in 1943 ranged from $6.91 to $17.86, slightly higher figures than for 1942. Average realizations for selected States in 1943 follow: Colorado, $6.91; South Dakota, $7.71; North Carolina-Tennessee, $11.80; and New Jersey (including marketed spar ground in Connecticut), $17.59.

According to E&MJ Metal and Mineral Markets, quoted prices for ground feldspar were the same during 1943 as reported for 1941 and 1942. Potash feldspar, f. o. b. North Carolina, 200-mesh, white, in bulk, was quoted at $17 per short ton, and soda spar, similarly prepared, at $19. Potash and soda spar, f. o. b. Maine, 200-mesh, white, in bulk, were listed at $17 and $19 per ton, respectively. Granular glass feldspar, f. o. b. North Carolina, 20-mesh, white, in bulk, was priced at $12.50 per ton, and semigranular glass spar at $11.75 per ton. Quotations on Virginia feldspar, as listed in the same journal, were: No. 1, 230-mesh, $18; 200-mesh, $17; glassmakers' spar, No. 18, $12.50, and No. 17, $11.75. Ground spar for enamelers' use ranged from $14 to $16 per ton f. o. b., either on a Spruce Pine, N. C., or Keene, N. H., basis.

CONSUMPTION AND USES

Crude feldspar.—Most crude feldspar is sold to merchant mills, which obtain their supply from a number of mines or localities. The raw spar is stock-piled and sorted according to grade and source, then blended and ground to specified purity and fineness and sold to ultimate consumers. However, a few pottery and enamel manufacturers have purchased part or all of their feldspar requirements crude and have ground it as needed in their own mills. Certain makers of soap, cleansers, and sweeping compounds also mine or purchase crude feldspar, largely from New England, Virginia, and North Carolina, and after grinding or otherwise processing it utilize the abrasive properties of the spar in their products. Manufacturers of artificial teeth annually use a small tonnage of carefully selected crude material, which must be free of all grit and is sold at a substantial premium over No. 1 grade commercial feldspar.

Ground feldspar.—Sales of ground feldspar to the ceramic industries in the United States annually constitute more than 95 percent of the total shipments. Most of the ground spar consumed is sold to glass and pottery manufacturers. Reflecting the higher output of glass products in 1943, shipments to the glass industry totaled 214,668 short tons, a record amount, and were 64 percent of the total sales, compared with 60 percent in 1942. Sales to potteries decreased to 29 percent or 3 points below the 1942 figure; however, the manufacture of vitreous porcelain was especially active owing to the increased war demand. Continued conversion of enamelware plants to the annealing of steel and to other war purposes, as well as lack of necessary priorities, cut shipments to these consumers in 1943 to about half those reported for 1942. Sales of feldspar for use in soaps and abrasives in 1943, however, were more than twice the 1942 level. The remainder of the ground spar sold by merchant mills in 1943 was utilized for miscellaneous ceramic purposes other than glass, pottery, or enamel and for various other purposes, most of them unspecified. A minor application with respect to tonnage but important to many war industries is its employment in welding-rod coatings.

Ground feldspar sold by merchant mills in the United States, 1941–43, by uses

Use	1941		1942		1943	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total
Ceramic:						
Glass	182,878	51.6	195,601	59.7	214,668	63.9
Pottery	127,140	35.9	106,081	32.4	97,887	29.2

Other uses	7,505	2.1	1,350	.4	5,366	1.6
	354,417	100.0	327,786	100.0	335,810	100.0

Shipments of ground feldspar into consuming States in 1943 indicated increased consumption in certain southern States, particularly West Virginia, Oklahoma, and Texas. Small increases also were noted in shipments to Indiana, Maryland, Massachusetts, and Wisconsin. Other States for which comparisons are possible showed smaller totals than in 1942. In 1943 shipments to Illinois comprised 15 percent of the total shipments; West Virginia, 15 percent; Ohio, 13 percent; Indiana, 12 percent; New Jersey, 12 percent; Pennsylvania, 11 percent; and New York, 5 percent. Sizable shipments also were made to Maryland, Oklahoma, Texas, and Wisconsin.

The following table shows shipments of ground feldspar for the 5-year period 1939–43, by destination of shipments as reported by merchant grinders.

Ground feldspar shipped from merchant mills in the United States, 1939–43, by destinations, in short tons

Destination	1939 [1]	1940	1941	1942	1943
California	7,590	7,897	10,444	12,224	8,669
Illinois	15,948	32,811	44,573	50,450	49,302

West Virginia	19,188	21,889	29,916	35,161	48,940
Wisconsin	5,134	6,967	10,517	7,837	8,718
Other destinations [3]	25,463	27,721	40,271	13,877	26,739
	256,769	285,713	354,417	327,786	335,810

[1] Data include 99 percent of total ground feldspar.

[2] Included under "Other destinations"; separate figure for State not available.

[3] Includes Arkansas, Colorado, District of Columbia, Hawaii, Kentucky, Louisiana, Maryland (1939–41), Massachusetts (1939–41), Michigan, Minnesota, Mississippi, Missouri, Oklahoma (1939–41, 1943), Puerto Rico, South Carolina, and Texas, and other States (shipments to which cannot be segregated); also small shipments to Canada, England, and Mexico.

NEPHELINE SYENITE

Nepheline syenite continued as an active competitor of feldspar in 1943. When first mined virtually the entire output was used in the manufacture of glass where its high alumina content proved to be both economical and beneficial. More recently, after extensive research had been undertaken, increasing amounts have been utilized in various types of ceramic bodies. Nepheline syenite of pottery grade is finely ground, whereas that for the glass trade is granular material. A residue or dust remaining from grinding operations is sold to enamel and colored-glass manufacturers, as a substitute for pumice for grinding and polishing, as a cleanser, and in the heavy-clay industries.

Nepheline syenite has not been produced commercially in the United States. Canadian production in recent years has been reported largely from Methuen Township, Peterborough County, Ontario; smaller quantities come from the Bancroft-Gooderham district, Hastings County, also in Ontario. Operation of the Port Coldwell deposit on the northern shore of Lake Superior, mentioned in Minerals Yearbook, 1942, apparently has not progressed beyond the development stage.

A large part of the Canadian output of nepheline syenite is shipped into the United States in crude form, principally to Rochester, N. Y., to be ground and distributed to consuming industries in this country. Some nepheline syenite, however, is ground before importation. Imports of crude nepheline syenite increased 20 percent in 1943 compared with 1942 and again reached a new high. Ground nepheline syenite imported into the United States in 1943 was slightly more than half the figure reported for 1941, although considerably in excess of that imported in other recent years. All receipts of crude and ground nepheline in this country originated in Canada.

Nepheline syenite imported for consumption in the United States, 1939–43

Year	Crude		Ground		Year	Crude		Ground	
	Short tons	Value	Short tons	Value		Short tons	Value	Short tons	Value
1939	29,231	$95,453	--------	--------	1942	35,990	$120,688	4	$44
1940	27,888	87,162	6	$25	1943	43,105	150,225	737	7,680
1941	35,799	112,101	1,359	13,695					

According to Canadian Chemistry and Process Industries, quotations on processed nepheline syenite during 1943 remained at the same levels as in 1942: Grade A, 20-mesh, bulk, in carlots, $11.75 per ton, f. o. b. Lakefield, Ontario; grade A, 200-mesh, bulk, in carlots, $16.50 per ton, f. o. b. Kingston, Ontario; and grade B, dust, bulk, in carlots, $10 per ton, f. o. b. Lakefield, Ontario.

Nepheline also is available as a byproduct of phosphate-rock recovery on the Kola peninsula in Soviet Russia. Some attempt has been made to use this material, but no production statistics have been published.

APLITE

Sales of ground "aplite" in 1943 were maintained at virtually the same high level as in 1942. By far the greater part of the output is marketed to glass manufacturers. Although of proved efficacy, extensive use of aplite, feldspar, or other feldspathic rocks for extinguishing incendiary magnesium bombs has not materialized.

The same two firms that operated in 1942 were actively engaged in the grinding of aplite in 1943: Dominion Minerals, Inc., Washington, D. C.; and Carolina Mineral Co., Erwin, Tenn. The grinding plants for both companies are near Piney River, Va.

TECHNOLOGICAL DEVELOPMENTS

Much interest has been manifest in the treatment of low-grade feldspar ores for the recovery of feldspar as a byproduct in flotation mills, designed primarily to treat other minerals. Two plants, including that of the Solvay Process Co., at Kings Mountain, N. C., that mill principally spodumene are marketing some byproduct spar. Two feldspar companies have reached the pilot-plant stage in the separation of feldspar by froth flotation. The Consolidated Feldspar Corporation also is building a new flotation plant at Kona, N. C., to treat the product of a 70-foot pegmatite containing 70 percent feldspar. The mica and quartz in the rock are so intimately associated with the spar that separation can be effected only by flotation. Scrap mica and commercial silica will be byproducts.

Iron-bearing feldspathic minerals are being actively investigated to find a way of removing the objectionable iron. One method consists of heating the minerals until friable, crushing and sizing, followed by magnetic separation.[2] Another process is designed particularly for treating aplite;[3] the rock is calcined at a temperature of 1,000° to 2,500° F. and acid-leached to dissolve most of the iron, the greater part of the original alumina content being unaffected. Fine grinding of feldspathic minerals with high quartz content to recover a high-grade spar has been described in a recent German patent.[4] In a paper delivered before the Milling Methods Division as a contribution to a symposium on flotation machines at the 1944 annual meeting of the American Institute of Metallurgical and Mechanical Engineers, the present status and possibilities in the froth flotation of feldspar and other minerals were discussed by S. H. Falconer and B. D. Crawford, of the Ore Dressing Laboratory of the American Cyanimid Co.

The use and effect of various opacifiers in feldspathic glaze compositions were studied by Beam.[5] Possible causes of variations in surface and other characteristics of electrical porcelain were sought in a study of the particle-size variation in commercial feldspars and flints.[6] Specific surface values were calculated. Unsuspected colloidal properties of some of the feldspars in the particle-size range below 3 microns were discussed.

Barium feldspars in Wales are described by Spencer.[7] Feldspar, principally soda spar, and a fluorspar-enriched product similar in composition to English Cornwall stone are produced in South Australia and shipped to other parts of that country.[8] Fluorescence of central European feldspars[9] and the minerals (including feldspar) of the Kirov district in the Murmansk region of the U. S. S. R. were studied by Chirvinskii.[10]

OTHER DEVELOPMENTS

Consolidated Feldspar Corporation was reported to have doubled the capacity of its mill at Louise, near Kingman, Ariz.[11] A brief description of the Strickland deposit at Portland, Conn., producing feldspar and mica from several operating mines, appeared about the middle of the year,[12] and the Big mine in Cheshire County, N. H., is reported again to be in operation, mining sheet mica and feldspar and recovering quartz and beryl as byproducts.[13] Milling operations at the Western Feldspar Milling Co. plant at Denver, Colo., are described by Torgerson.[14] Both feldspar and fluorspar are processed. Current milling practice at the Minpro unit of the United Feldspar & Minerals Corporation, near Spruce Pine, N. C., was described in detail in the trade press.[15]

IMPORTS

Feldspar.—Imports of feldspar into the United States in 1943 increased 25 percent in tonnage and 43 percent in value compared with 1942; average value per ton rose more than a dollar and reached $8.40 compared with $7.33 in 1942. The total value of the 1943 imports was the highest since 1930. As in former years, all imports originated in Canada.

Feldspar imported for consumption in the United States, 1939–43

Year	Crude		Ground		Year	Crude		Ground	
	Long tons	Value	Short tons	Value		Long tons	Value	Short tons	Value

Cornwall stone.—Although receipts in 1943 of both unmanufactured and ground Cornwall stone were several times those reported for 1942, imports were very much smaller than in most years preceding 1942. The United Kingdom is the sole source of supply. Continuing the trend of recent years, average values (foreign market value) in 1943 again increased—unmanufactured Cornwall stone to $14.26 per long ton compared with $13.80 in 1942, and ground material to $22.10 per ton compared with $18.40 in 1942.

Cornwall stone imported for consumption in the United States, 1939–43

Year	Unmanufactured		Ground		Year	Unmanufactured		Ground	
	Long tons	Value	Long tons	Value		Long tons	Value	Long tons	Value
1939	1,684	$17,233	348	$3,965	1942	74	$1,021	5	$92

1941	2,736	31,138	182	2,658					

WORLD PRODUCTION

The United States is by far the largest producer of feldspar. Other countries reporting sizable outputs or exports in normal years have been Sweden, Norway, Germany (Bavaria), Canada, Finland, Czechoslovakia, and China, although no official figures for the last two nations mentioned have been published. Argentine and Australian shipments have increased in recent years, and Canadian shipments in 1943 were 16 percent higher than in 1942.

World production of feldspar from 1938 through 1943, so far as data are available, appears in the following table.

World production of feldspar, 1937–43, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1937	1938	1939	1940	1941	1942	1943

SUMMARY

Sales of asbestos of domestic origin in 1943—6,014 short tons—were 61 percent less than in 1942. Sales of chrysotile declined greatly, but those of amphibole showed little change. Most of the domestic production consists normally of the shorter grades of chrysotile, but the principal producer of these grades suspended operations temporarily in 1943 while opening up a new quarry. Because of the great decline in output, United States sales furnished only 1 percent of domestic requirements.

Canada supplied the larger part of United States needs of chrysotile, but the Canadian output consists chiefly of the nonspinning shorter grades. African chrysotile was imported in substantial quantities to supplement the supply of Canadian spinning fibers. Soviet Russia, Australia, and India are other sources.

Asbestos is an important mineral in the military program. The United States depends almost entirely for its supply of the critical grades on imports from Canada, Southern Rhodesia, and the Union of South Africa. The domestic contribution of critical grades is negligible.

Three types of asbestos—chrysotile, amosite, and blue—are needed for military use. Chrysotile grades fall in two categories—long fibers suitable for textiles and short fibers used in making asbestos paper, millboard, insulating cements, and a variety of asbestos-cement products such as shingles, flat and corrugated siding, and pipe. The long fibers equivalent to Canadian Groups 1, 2, and 3 and Rhodesian Grades C & G1 and C & G2 are regarded as critical because they are much in demand, and supplies are not as abundant as desired. Aside from a considerable tonnage used in sheet packing, the long fibers are employed in asbestos textiles. Their more important uses are in Navy cable, friction materials, packings and gaskets, cloth for the Maritime Commission and Navy, laminated plastics, and aircraft tape. The Rhodesian fibers are lower in iron than the Canadian; for this reason, their use is required for textiles used in Navy cable construction where electrical insulation is important. Supplies of asbestos textiles are short, and therefore they are carefully controlled and allocated under the provisions of Order M-283.

Amosite, mined only in Africa, is a critical variety that has important military uses, including woven insulation for ship work, 85-percent magnesia and other high-temperature molded insulations, fireproof marine insulating board, and sprayed-asbestos insulation. It is difficult to increase the production of amosite, and future requirements are not assured for as long a period as is desirable.

Blue asbestos, Grades MS and S, are imported from the Union of South Africa chiefly for the manufacture of asbestos-cement pipes, which have performed important functions as substitutes for iron pipe, thus freeing iron for more direct military uses. The supply of blue asbestos appears to be adequate, and therefore these grades were not as critical at the end of 1943 as they were early in the year.

Conservation Order M–79, as amended October 1, 1943, restricted the end uses of Rhodesian C & G1 and C & G2 and amosite Grades B–1, B–3 or D–3, and 3/DM–1 and placed certain restrictions on Canadian spinning fibers. One of its most important requirements was the stipulation that 1 ton of Rhodesian C & G3 be used with every 5 tons of Canadian Grade 3R in textile manufacture. Rhodesian C & G3 has always been regarded as a shingle fiber unsuited for textile use; but, with the cordial cooperation of manufacturers, large quantities of this lower-grade fiber were worked into textile products, thereby avoiding what might have been a serious shortage of spinning fibers.

In 1943 the entire supply of critical grades imported from the Union of South Africa and Rhodesia was purchased by the Metals Reserve Co. and allocated in accordance with the more urgent needs. The same procedure will be followed in 1944, although it is possible that blue fibers will be exempted from this requirement and will be handled through private negotiations. The Combined Raw Materials Board determines the distribution, between the United Kingdom and the United States, of the available supply of all critical grades.

Ample supplies of the shorter grades of chrysotile fibers were imported from Canada in 1943. Anthophyllite and tremolite, varieties of asbestos that are generally weak and brittle, are employed for welding-rod coatings, acid filters, and insulating cements, and as fillers in some products. They are produced in several countries but enter international trade to a very limited extent.

Salient statistics for asbestos in 1942 and 1943 are summarized in the following table.

Salient statistics of the asbestos industry in the United States, 1942–43

	1942		1943	
	Short tons	Value	Short tons	Value
Domestic asbestos—				
Produced:				
Chrysotile	13,109	(1)	1,731	(1)
Amphibole	2,208	(1)	2,214	(1)
Total produced	15,317	(1)	3,945	(1)
Sold or used by producers:				
Chrysotile	13,373	$480,245	3,900	$302,289
Amphibole	2,108	18,612	2,114	32,526
Total sold or used by producers	15,481	498,857	6,014	334,815
Imports (unmanufactured)	419,242	21,217,650	440,255	23,053,524
Exports (unmanufactured)	774	134,411	364	34,355
Apparent consumption [2]	[3] 433,949	[3] 21,582,096	445,905	23,353,984
Exports of asbestos products	(1)	5,116,919	(1)	4,876,500

[1] Figures not available.
[2] Quantity sold or used by producers, plus imports, minus exports.
[3] Revised figures.

The following table shows domestic production of asbestos during recent years according to varieties:

Asbestos sold or used by producers in the United States, 1939–43, by varieties

Year	Chrysotile		Amphibole		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1939	15,043	$503,097	416	$9,691	15,459	$512,788
1940	18,672	664,520	1,388	9,988	20,060	674,508
1941	22,439	707,589	1,952	18,164	24,391	725,753

1943	3,900	302,289	2,114	32,526	6,014	334,815

DOMESTIC INDUSTRY

REVIEW BY STATES

Arizona.—Sales of Arizona asbestos in 1943 totaled somewhat less than in 1942, but the value was considerably higher. Sales were made by the following companies: Arizona Chrysotile Asbestos Co., Arthur Enders, and Guy G. Phillips, all of Globe; Earl Pierce, of Young; and Johns-Manville Products Corporation, 22 East 40th Street, New York, N. Y., with mine and mill at Chrysotile.

High-grade iron-free chrysotile asbestos like that obtainable in Arizona has important special uses in the war program. Accordingly the Reconstruction Finance Corporation has authorized a loan of $25,000 to Pine Top Asbestos Mines which, supplemented by about $17,000 from other sources, will be used to develop properties of the company 37 miles northeast of Globe. The Defense Plant Corporation has agreed to advance $80,000 to the company for building a mill to handle the product of its own mines and to serve as a custom mill for small producers in the region. Limited progress had been made on these projects by the end of 1943.

California.—The only producer of asbestos in California making sales in 1943, as in 1942, was Kohler & Chase, miners of short-fiber chrysotile near Monticello, Napa County.

Georgia.—Production of asbestos in Georgia in 1943 was less than half as great as that in 1942. The only operator was again the Powhatan Mining Co., from its amphibole asbestos property near Dillard, Rabun County.

North Carolina.—Sales of asbestos in North Carolina were considerably larger in 1943 than in 1942. The Industrial Minerals Corporation, operating at Newdale, Yancey County, is the largest producer of amphibole asbestos in the United States. Substantial quantities were sold, chiefly for welding-rod coating. W. T. Hippey also produced a considerable tonnage of anthophyllite at Micaville, Yancey County.

Oregon.—Philip S. Hoyt and Mrs. Flora Winsenberg reported sales of small tonnages of tremolite asbestos to be used in making acid filters. The properties are near Grants Pass, Jackson County.

Vermont.—The Vermont Asbestos Mines Division of the Ruberoid Co. discontinued operation of its open-pit mine adjacent to the mill near Eden, Vt., but has developed a new operation in asbestos-bearing rock on the opposite slope of Belvidere Mountain. Rock from this source is conveyed over the mountain by an overhead cableway about 1 mile long. The deposit, which is said to be extensive, furnishes chrysotile fiber of nonspinning grades. Because of the change in source of raw material there was no production during 1943, but it was expected that the new tramway would come into operation with the advent of favorable weather in the spring of 1944 and that the mill would attain a normal rate of production during ensuing months. Asbestos sales during 1943 were made from stock on hand.

TRENDS IN CONSUMPTION

Domestic consumption of unmanufactured asbestos and value of exports of asbestos products during the past 20 years are indicated in the accompanying table. Consumption broke all previous records in 1943 and exports of asbestos products were exceeded in value only by those of 1942. The latest year for which the Bureau of the Census published data on manufactured asbestos products was 1939, when their value was $97,944,735.

Raw asbestos consumed in and asbestos products exported from the United States, 1924–43

Year	Raw asbestos—apparent consumption (short tons)	Asbestos products—exports (value)	Year	Raw asbestos—apparent consumption (short tons)	Asbestos products—exports (value)
1924	182,280	$2,529.795	1934	123,752	$2,142,514
1925	230,669	2,383,325	1935	174,655	2,261,929
1926	257,875	3,481,814	1936	250,922	2,479.273
1927	226,365	2,687,086	1937	316,263	3.047,078
1928	231,984	3.999,022	1938	187,150	2,533.916
1929	264,873	4,640,599	1939	255.547	3,354,920
1930	212,152	4,193,510	1940	262,199	3,473.248
1931	137,875	2,606.166	1941	438,741	4,835,194
1932	98,606	1,608,880	1942	[1] 433,949	5,116,919
1933	122,909	1,743,140	1943	445,905	4,876,500

[1] Revised figures.

The customary correlation of the asbestos industry with the manufacture of automobiles because of the importance of asbestos in brake bands and clutch facings is of no significance under current conditions, because automobile manufacture has been virtually suspended and has been superseded by the manufacture of airplanes, tanks, army trucks, jeeps, and mobile artillery, which have been and are being made in vast numbers. The large tonnages of asbestos formerly employed in commercial and pleasure cars now perform similar functions in military equipment. Other important uses are as packings, gaskets, boiler lagging, and pipe coverings at industrial plants. All these activities are included under industrial production, most of which was geared more or less directly to the military program in 1943.

Asbestos also finds wide application in the building industry, where it is employed for heat insulation and fireproofing. In this field also military construction has absorbed large quantities of asbestos products normally employed in private building.

The relation of asbestos consumption to industrial production and building construction is indicated in figure 1. The trends are strikingly similar from 1933 to 1941, but since that time industrial production has risen to such unparalleled heights that asbestos consumption could not keep pace with it. Asbestos production and fabrication had approached 100 percent of capacity, and importations from Africa had reached the limit of available transportation facilities by the end of 1941. Efforts to increase mine and mill output in 1943 were hampered to some extent by shortage of labor. The demands of greatly increased manufacturing activity have been met by careful conservation and by allocation of the critical grades of raw asbestos and their most essential products to urgent war needs. Credit for maintaining supplies in balance with war demands may be given to the War Production Board, the Combined Raw Materials Board, and the cordial cooperation with these agencies by the asbestos-producing and the manufacturing industries.

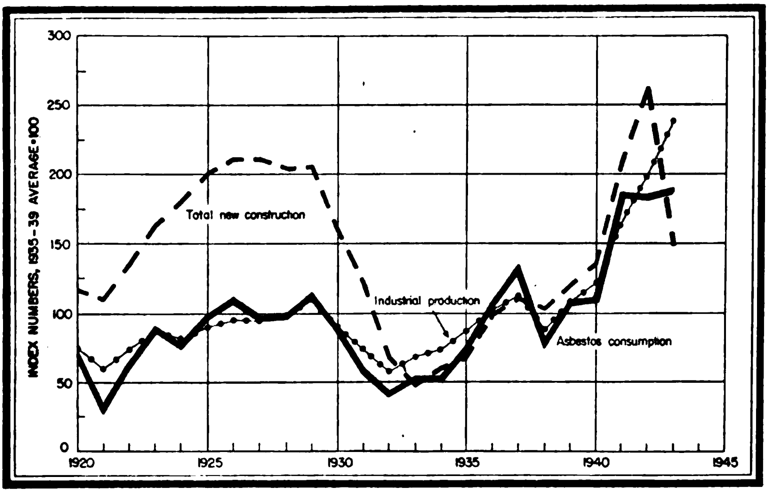

FIGURE 1.—Consumption of asbestos compared with total new construction and industrial production, 1920–43. Units are reduced to percentages of the 1935–39 average. Statistics on value of construction from the Bureau of Foreign and Domestic Commerce and on industrial production from the Federal Reserve Board.

MARKET CONDITIONS

Market trends throughout the year veered consistently from civilian to war needs. Demands were heavy, particularly for the long fibers. Supplies of spinning fibers were little in excess of immediate needs. Short fibers were adequate at all times to meet market requirements. While demands of private builders lagged, the requirements of asbestos-cement-products manufacturers were stimulated to some extent by the call for nonstrategic materials to substitute for critical metals.

PRICES

Prices of asbestos as quoted in E&MJ Metal and Mineral Markets show no change in 1943 from those quoted in 1942, which are given in full in the chapter on Asbestos in Minerals Yearbook, 1942, and therefore need not be repeated here.

NEW DEVELOPMENTS

Research work is now being conducted in Canada on a process for recovering magnesium chloride from serpentine tailings in the Quebec asbestos area. Magnesium chloride is used as a source of metallic magnesium, now employed extensively in the manufacture of munitions, which may find wide use under peacetime conditions. Profitable utilization of this waste product in Quebec is highly desirable because the spoil banks now comprise over 200,000,000 tons and are being increased at a rate of about 20,000 tons a day. Possible byproducts are salt cake, chlorine, silica, iron oxide, and chromite. A similar waste-utilization problem exists at all chrysotile-asbestos mining centers.

A new sound-deadening and vibration-reducing material having the trade name "Vibeston" is designed for use in airplanes to protect the hearing of flyers and to extend the life of the plane. No data are now available on its composition, but asbestos is an important component.

Glass wool is used to some extent as a substitute for asbestos in making wire coverings and some heat-insulating products, but asbestos is generally regarded as indispensable in making friction equipment. However, claims have recently been made that aluminum wool impregnated with rubber will give satisfactory service in automobile brake bands.

Interest has been renewed in a deposit of long-fiber chrysotile of good quality in northwestern Alaska on Dahl Creek, a tributary of the Kobuk River. Samples from this deposit were first sent to the Bureau of Mines in 1932. The deposit evidently consists of slip-fiber veins, the largest of which, according to present knowledge, is 3 inches across. The extent of the deposit has not yet been determined.

A use for asbestos that has attained recent prominence is in making protective asbestos felt to prevent corrosion of petroleum pipe lines. The pipe is first coated with tar, then by asbestos felt wound spirally. The Big Inch pipe line required 36,100 square feet of such felt per mile and the Little Inch 30,100 square feet per mile. However, the entire length of the pipe lines was not thus covered.

A special asbestos product, the nature of which cannot be disclosed at this time, has been developed for use as a rust-preventive coating for artillery in Africa where ordinary coatings are inadequate to resist the intense heat.

A new asbestos-cement product sold under the trade name "Stonewall" is said to be particularly adapted to replace metals urgently needed for war uses. The material may be applied to many types of construction.

POST-WAR OUTLOOK

Although asbestos has important war uses, many of them are equally applicable to a peacetime economy. For instance, asbestos gaskets, packings, and heat-insulating products now used in munition plants are employed in just the same ways in factories producing peacetime civilian goods. It is expected therefore that post-war asbestos consumption will approximate that of the years immediately preceding the war. It is possible, however, that the use of certain substitutes already mentioned will tend to reduce consumption to some extent.

Domestic output has never furnished more than a small fraction of domestic requirements. Although there is always the possibility of new and extensive discoveries, the expectation of finding them is remote, and there is little prospect of any substantial change in the domestic situation.

FOREIGN TRADE[1]

The following table shows imports of unmanufactured asbestos into the United States in 1942 and 1943. Total imports show a moderate advance in 1943. The most striking change, which reflects a marked improvement in the shipping situation, is an increase in imports of the high-grade African fibers of strategic quality to nearly double the quantity imported in 1942. Such large receipts of African asbestos were fortunate in view of the substantial decline in imports of Canadian crudes. The value of imports, which exceeded $23,000,000, was the highest in the history of the industry.

Asbestos (unmanufactured) imported for consumption in the United States, 1942–43, by countries and classes

[1] In addition to countries listed asbestos is produced in Bulgaria, Czechoslovakia, and Madagascar.

[2] Data not available.

[3] Estimate.

[4] Exports.

[5] Exclusive of sand, gravel, and stone (waste rock only), production of which is reported as follows: 1937, 3,611 tons; 1938, 2,975 tons; 1939, 3,535 tons; 1940, 5,880 tons; 1941, 7,669 tons; 1942–43, data not available.

[6] Includes asbestos flour.

[7] Imports into United States.

[8] Preliminary.

[9] January to September, inclusive.

CANADA

Canadian asbestos consists entirely of chrysotile, and all of it comes from the adjacent production centers of Thetford Mines, Black Lake, East Broughton, Vimy Ridge, and Asbestos in the Province of Quebec. Production has been continuous since 1878, and reserves are still very extensive.

The largest mine in the Quebec area is that of the Canadian Johns-Manville Co., Ltd. Other producers are Asbestos Corporation, Ltd., Johnson's Co., Bell Asbestos Mines, Ltd., Asbestos Crude & Fiber Mines, Ltd., Nicolet Asbestos Mines, Ltd., and Quebec Asbestos Corporation, Ltd.

Short fibers are the most abundant. A very small proportion of the total output consists of spinning fiber, and during recent years a downward trend in this proportion has been noted. This tendency is unfortunate at present, when the spinning grades are in greatest demand. The block-caving method of mining has been employed in the region for some years; and although it is more economical than deep open-pit work, especially for winter operation, the drop in percentage of crudes recovered is attributed to this newer method of mining, chiefly because there is limited opportunity for hand cobbing.

The following figures have been released by the Department of Mines, Province of Quebec.

Sales of asbestos in Canada, 1942–43, by grades

	1942			1943		
	Short tons	Value		Short tons	Value	
		Total	Average per ton		Total	Average per ton
Grade:						
Crudes	2,890	$1,233,184	$426.71	2,016	$888.099	$440.53
Fibers	199,829	15,339,128	76.76	217,889	16,071,843	73.76
Shorts	236,741	6.090.971	25.73	247,291	6,209.563	25.11
	439,460	22,663,283	51.57	467,196	23,169,505	49.59
Rock mined	8,233,516			7,929,469		
Rock milled	6,795,459			6,828.532		

AFRICA

Southern Rhodesia.—No figures for Rhodesian asbestos production have been published since May 1940. Export data, however, are available, and as local sales are quite small exports are an approximate measure of production. It is apparent from the accompanying table that production in 1942 was the highest on record.

Asbestos produced in Southern Rhodesia, 1939–43

Year	Short tons	Value	Year	Short tons	Value
1939	58,313	£1,088,782	1942 [1]	62,332	£1,811,042
1940 [1]	57,891	1,419,566	1943	[2]	[2]
1941 [1]	54,224	1,419,405			

[1] Exports.
[2] Data not available.

Union of South Africa.—The principal output of asbestos in the Union of South Africa consists of amosite, a variety produced commercially nowhere in the world except in the Transvaal. Crocidolite (blue asbestos) is next in importance. Incomplete figures indicate that the total yield in the Union in 1943 was a little higher than that in 1942 and the highest in the history of the industry. The following table shows production during recent years.

Asbestos produced in the Union of South Africa, 1939–43, by sources

Year	Short tons				Total value
	Transvaal	Cape Province	Natal	Total	
1939	15,827	6,144	79	22,050	[1] £517,535
1940	21,011	6,381	(2)	27,392	[3] 934,417
1941	[4] 21,704	[4] 6,576	(2)	[4] 28,280	[3] 990,756

Anthophyllite (Transvaal)	12	78	59	65	[3] 73
	22,050	27,392	28,280	34,559	[5] 35,000

[1] Data from Union of South Africa, Department of Mines, Quarterly Reports.
[2] Partly estimated.
[3] January to September, inclusive.
[4] Includes 79 tons produced in Natal.
[5] Preliminary total for year.

Swaziland.—The Havelock mine began production in June 1939 and yielded about 18,000 tons in 1940. No figures are available for later years because of war restrictions, but its output has increased considerably and it probably operated at capacity in 1943. The output consists of chrysotile.

SOVIET RUSSIA

Russian asbestos deposits are extensive, and the quality of the fiber is good. The Soviet Union is unique among all important asbestos-producing countries in that it is also a large consumer of asbestos. No figures for production are available since 1938, when an output of 86,000 tons was reported. A large asbestos-products-manufacturing industry had been established before the war, and it seems probable that the industry has been expanded to provide for the automotive needs of the immense army. Asbestos-cement products are doubtless in heavy demand also for rebuilding war-devastated areas. Lack of Russian statistics leaves a wide gap in the world record of this important industry.

OTHER COUNTRIES

Organization of the Australian Blue Asbestos Co., Ltd., capitalized at £100,000, is reported by the foreign press. This company will engage in mining and processing high-grade blue asbestos in the Hamersley Ranges of Western Australia. The output will be marketed through the building materials division of the Colonial Sugar Refining Co. Small quantities of asbestos from this source now reach United States markets.

According to a recent report,[2] the origin of the fiber is quite similar to that of the blue asbestos occurring in South Africa. The deposits are said to be extensive, and with improved transportation facilities an important industry may be developed in this area.

The Bolivian blue asbestos industry has been almost dormant since the loss of its former markets in Japan, but sales to consumers in Argentina were reported in 1943.

No further progress was reported in 1943 on construction of the new mill or development of the chrysotile asbestos property near Tinaquillo, Venezuela.

According to news reports, a promising deposit of asbestos has been located near Yarumal, State of Antioquia, Colombia, South America. No data are available as to the nature or quality of the fiber.

World production	1488		
Ground (and crushed)	1400		
Sales	1490		
Prices	1491		

SUMMARY

The most severe shortage of barite since World War I developed in the last few months of 1943, owing in part to increased demands for barite in well drilling, lithopone, chemicals, glass, and fillers and in part to the labor shortage. The labor shortage was caused by the requirements of Selective Service and by low wages, originally the result of low barite prices. Producers and Government agencies collaborated in the latter part of 1943 and the early months of 1944 in working out adjustments in wages and prices that would result in increased production. In Georgia and Tennessee wage increases approved by the War Labor Board were generally 10 to 15 cents an hour, and price increases approved by the Office of Price Administration $1 to $2.50 a long ton. Missouri wages and prices had not been settled by June 1, 1944; producers there were asking approximately 10 to 15 cents an hour increase for labor and $1.50 a short ton increase in the price of barite.

The production of crude barite in the United States in 1943 was 429,298 short tons compared with 449,873 tons in 1942. Consumption in 1943 was 434,774 tons, distributed as follows: For well drilling, 144,452; for chemicals, 81,547; for lithopone, 128,073; for glass, 25,464; for paint filler, 15,000; for rubber filler, 8,000; and for other purposes, including grinding losses, 32,238.

Salient statistics of the barite, witherite, and barium chemical industries in the United States, 1939–43

	1939	1940	1941	1942	1943
Barite:					
Crude:

[1] F. o. b. mine shipping point.

[2] Declared value f. o. b. foreign market.

[3] Barite sold or used by producers plus imports.

[4] Data for 1941–43 are calculated on a different basis from that used for 1939–40. Sales figures for 1939–40 include the producer's own consumption of barium chemicals in materials which the producer sold without further conversion; for example, where the firm produced blanc fixe and used it as an extender in titanium pigments such blanc fixe is included in "Sold by producers" in the 1939–40 data, but in the 1941–43 data it is not included in "Sold by producers" but is included in "Used by producers"; see table, "Barium chemicals produced and used or sold by producers in the United States, 1941–43." Data in 1939–40 do not include sales of barium chemicals made from purchased barium chemicals; for example, if a firm bought barium carbonate and converted it to barium nitrate, such barium nitrate is not included in "Sold by producers"; in 1941–43 such barium nitrate is included in "Sold by producers." In 1941–43 sales by one producer to another are not included in "Sold by producers" if the purchased material was used by the purchaser in the year reported; jobbing activities or resale of purchased material are not included.

[5] Exclusive of cadmium lithopone.

BARITE

CRUDE

PRODUCTION AND CONSUMPTION

Both production and consumption of crude barite were well maintained during the first half of 1943. Demand for barite in well drilling had slowed considerably in 1942 but increased in each quarter of 1943. Consumption of barite in lithopone, barium chemicals, glass, and fillers fluctuated very little during the first three quarters of 1943. On the whole, production met demand during the first three quarters of 1943, but in the fourth quarter a variety of circumstances converged to create a serious shortage. Factors contributing to the deficit were the manpower shortage, low wages, low prices, depletion of deposits, and increased demand in nearly all uses.

However, it seemed generally evident that the paramount cause of the shortage was lack of labor, a condition that was felt most severely in Tennessee and Georgia, though evident also in Missouri. A medium-size barite washer requires, as a minimum crew: 1 shovel operator, 5 truck drivers to haul the barite-bearing clay to the washer, 3 to 5 men at the bull pen (where the clay is broken up with a heavy stream of water, allowing the lumps of barite to fall through a grizzly into the log washer), 1 jigman, 1 mechanic, 1 watchman, and 1 foreman, a total of 13 to 15 men per shift. If two or three shifts are operated, the number of workers in each category (except the mechanic and watchman) must be doubled or tripled accordingly. Various schemes for the reduction of personnel have been proposed or put into effect during the first half of 1944. The Paga Mining Co., Cartersville, Ga., faced with a shortage of both trucks and drivers, installed a 1,700-foot pipe line from the cut to the washer. The barite is crushed at the cut and pumped as a slurry back to the washer. One Missouri operator has taught his truck drivers to operate a power shovel and to fill their own trucks, thus dispensing with a shovel operator.

Wages paid in Georgia and Tennessee during September 1942, "frozen" by Public Law 729, 77th Congress, 2d Session, effective October 2, 1942, were as follows: Common labor, 40 cents an hour; semiskilled labor (truck and tractor drivers, jigmen, and washermen), 40 and 45 cents an hour; and skilled labor (shovel operators, mechanics, welders, and carpenters), 60 to 78 cents an hour. The War Labor Board approved wage increases as follows: Common labor, 50 cents; semiskilled labor, 55 cents; and skilled labor, 80 cents an hour. Producers in Washington County, Mo., were asking similar wage increases for their employees, though with a wider range of permissive payment. Negotiations had not been completed by June 1, 1944.

Hand-mining of barite in Missouri, an industry of small proportions in recent years, faces further drastic curtailment because of a National Labor Relations Board finding[2] that hand miners were employees of the owners or lessees of the land being mined, to the extent that the landowners or lessees must bargain collectively with union representatives of the miners. The landowners, who previously understood the miners to be independent contractors, are now generally reluctant to let hand miners dig barite on their property, as they believe that the diggers, as employees, would have to be paid minimum wages of 40 cents an hour, a wage level which, it is claimed, discourages production by slow pick-and-shovel methods. The National Labor Relations Board decision was affirmed in the United States Circuit Court of Appeals for the Eighth Circuit[3] on November 4, 1942, and a writ of certiorari was denied by the United States Supreme Court on April 19, 1943.[4]

Some barite is still dug in the classical pick-and-shovel manner, but the quantity, as estimated from consumer's purchases, probably did not exceed 8,000 or 9,000 short tons in 1943.

To strengthen the financial position of barite miners, thus indirectly encouraging barite production, the Congress provided for a "depletion" deduction in filing income taxes. The Revenue Act of 1943 (Public Law 235, 78th Congress, 2d Session), Section 124 (a) (4) (A) states:

> In General.—The allowance for depletion * * * shall be, in the case of * * * barite, * * *, 15 per centum * * * of the gross income from the property during the taxable year, excluding from such gross income an amount equal to any rents or royalties paid or incurred by the taxpayer in respect of the property.

The War Production Board Materials Substitution and Supply List, Issue 12, April 15, 1944, classed barite in group I, F, for purposes of determining priorities and for indirect assistance to local Selective Service boards in determining the essentiality of barite miners.

[1] A plant producing more than 1 product is counted but once in arriving at State totals.

PRICES

Barite prices in 1943 were frozen as of the individual producer's highest price in March 1942 (as provided by Maximum Price Regulation 327, February 22, 1943, of the Office of Price Administration). In Georgia and Tennessee regular chemical-grade barite sold at $8 and $8.50 a long ton. Price ceilings approved by the Office of Price Administration, April 8, 1944, ranged from $9.50 to $11 a long ton.

Most Missouri producers had been selling chemical grade barite at $7 a short ton f. o. b. rail point when their prices were frozen by Office of Price Administration. Producers' requests for an area price of $8.50, effective for Washington County, Mo., were still pending on June 1, 1944. Missouri barite prices have varied widely in the past 80 years, for example (per short ton): 1861, $7; 1882, $8; 1890, $5; 1901, $3.52; 1910, $3.29; 1920, $10.17; 1930, $7.08; and 1940, $6.30.

WORLD PRODUCTION

Data on production of barite in foreign countries have been meager since the outbreak of war. Available figures are shown in the following table.

World production of barite, 1937–43, by countries, in metric tons [1]

[Compiled by B. B. Waldbauer]

Country [1]	1937	1938	1939	1940	1941	1942	1943

United States	327,380	304,298	331,910	354,219	438,523	408,116	389,451

[1] In addition to the countries listed, barite is produced in China, Czechoslovakia, Eire, Japan, and U. S. S. R., but data on production are not available.

[2] Data not available.

[3] Official figures which, it is reported, cover only output of mines included under the mining law.

[4] January to September, inclusive.

Canadian Industrial Minerals, Ltd., has been mining and grinding barite near Walton, Nova Scotia, for oil-well drilling in Trinidad and Venezuela since 1941, and shipments in 1943 reached 20,135 short tons. Lithopone and barium-chemical manufacturers in the United States investigated the possibility of using crude Nova Scotia barite, and one lithopone producer bought a substantial trial shipment in the spring of 1944. The material appeared satisfactory for use in lithopone, but its strontium and calcium content may prove detrimental for chemical use. A typical analysis of Nova Scotia barite is Ba (as $BaSO_4$) 95.75, Ca (as $CaSO_4$) 1.80, Sr (as $SrSO_4$) 1.09, SiO_2 0.69, Fe_2O_3 0.76, Mn 0.04 percent, and F trace. Reserves, originally estimated at 1,500,000 tons, have been extended 250,000 tons by recent drilling.[6]

Barite is also produced near Golden, British Columbia, mostly for oil-well drilling. Total production of barite in Canada in 1943 was 24,474 short tons valued at $255,525 (Canadian) compared with 19,667 tons valued at $188,144 in 1942 and 6,890 tons valued at $74,416 in 1941.

The barite industry in Australia was reviewed in Mineral Trade Notes.[7] From 1885, when barite was first produced in Australia, until the end of 1942, 72,485 short tons were produced in the country. South Australia is the leading producing State, with a total output from 1910 to 1942, inclusive, of 58,064 tons; New South Wales ranks second. All production is from lenses and veins. The most productive area is said to be 2 miles south of Noarlunga, which is 24½ miles by rail from Adelaide. Consumption of barite in Australia in normal times is divided approximately as follows: 55 percent in paint, 19 in rubber, 9 in fillers, and the remainder in various products, including paper, batteries, glass, and chemicals. Neither lithopone nor blanc fixe is made in Australia at present, all requirements being imported. November 1943 prices of crude barite f. o. b. Adelaide were quoted at £6 to £3 a short ton, depending on grade.

GROUND (AND CRUSHED)

SALES

Ground barite is used chiefly to weight oil-well drilling muds so that oil and gas may be confined to their levels and blow-outs prevented. The revival of well drilling in the last few months of 1943 placed considerable strain on facilities for grinding barite and led the Magnet Cove Barium Corporation and the National Lead Co. to enlarge their flotation plants at Malvern, Ark. The former built a complete second plant, whereas the latter installed individual units of larger capacity in its regular plant.

A shortage of glass barite seemed imminent in 1943, owing to the decreased production of Wolf River Corporation near Sweetwater, Tenn. However, experiments proved that glassmakers could use ground barite instead of the coarser crushed material formerly thought necessary. Barite is used in the glass batch to flux surface froth, which insulates the melt from furnace gases and slows heat transfer. Magnet Cove Barium Corporation, an affiliate of the Wolf River Corporation, undertook to supply the markets relinquished by Wolf River Corporation.

A considerable quantity of ground barite is bleached for use as a filler in white paints, rubber, cloth, wall paper, printing ink, and plastics. Unbleached barite may be used where a brown filler is permissible—for example, in linoleum, phonograph records, rope finishing, asbestos brake linings, and dark paints and rubber.

The following firms reported production of crushed or ground barite to the Bureau of Mines in 1943: Barium Products, Ltd., Newark, plant at Modesto, Calif.; Baroid Sales Division, National Lead Co., 830 Ducommun St., Los Angeles, Calif., grinding plants at Malvern, Ark., El Portal, Calif., and Fountain Farm, Mo.; Chemical and Pigment Division, The Glidden Co., Oakland, Calif.; Clinchfield Sand & Feldspar Corporation, 618 Mercantile Trust Bldg., Baltimore, Md., plant at Kings Creek, S. C.; Commercial Minerals Co., Inc., 310 Irwin St., San Francisco, Calif.; De Lore Division, National Lead Co., P. O. Box 2808, Carondelet Station, St. Louis, Mo.; Industrial Minerals & Chemical Co., 6th and Gilman Sts., Berkeley, Calif.; Magnet Cove Barium Corporation, Malvern, Ark.; George S. Mepham Co., 2001 Lynch St., East St. Louis, Ill.; Milwhite Co., Inc., Houston, Tex.; F. E. Schundler & Co., Inc., 600 Railroad St., Joliet, Ill., and 45 Vernon Ave., Long Island City, N. Y.; Southwark Manufacturing Co., Camden, N. J.; Thompson-Weinman Co., Cartersville, Ga.; Wolf River Corporation, Jamestown, Tenn.; and L. A. Wood Co., Sweetwater, Tenn.

Ground (and crushed) barite sold or used by producers in the United States, 1939–43

	1939	1940	1941	1942	1943
Plants	13	16	16	19	18
Short tons	170,695	184,390	234,877	178,765	208,252
Value	$2,902,973	$3,697,806	$4,606,882	$3,611,745	$3,743,919

Ground (and crushed) barite sold or used by producers, 1941–43, by consuming industries

Industry	1941		1942		1943	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total
Well drilling	154,760	66	117,380	66	144,452	69
Paint	31,009	13	18,484	10	15,000	7
Glass	22,615	10	21,895	12	25,464	12
Rubber	9,800	4	6,334	4	8,000	4
Undistributed	16,693	7	14,672	8	15,336	8
	234,877	100	178,765	100	208,252	100

Data in the foregoing table were compiled from grinders' estimates and may be somewhat inaccurate; however, figures covering consumption in well drilling and glass—the two largest individual uses—appear to be accurate, as the number of producers for these uses is small, and their figures showing actual shipments by firms were available to the Bureau of Mines. Consumption of ground barite in "Paint," "Rubber," and "Undistributed" has been estimated partly by the grinders and partly by the Bureau of Mines.

The Paga Mining Co., Cartersville, Ga., began operating in May 1944 its new auxiliary plant to recover barite fines from washer waste waters by tabling and flotation. Formerly 5 to 7 percent of the barite in the clay matrix was lost in the washing operation; the new plant is designed to recover the greater part of these fines, most of which fall within a range of 10- to 80-mesh.

PRICES

The price of ground barite delivered to oil wells in the Houston (Tex.) area was $23 to $27 a short ton in 1943. The royalty payment of $13 a ton is no longer required, as the patent on the use of barite in well drilling expired in 1943.[8] Ground, bleached barite, according to the Oil, Paint and Drug Reporter, was quoted at $25.35 a short ton in bags, carlots, at St. Louis, Mo. Unbleached material was quoted at $17.50 a short ton, bags, carlots, f. o. b. producing plant. Crushed barite for glass use was quoted at $11.50, $12.50, and $13.50 a long ton, bags, f. o. b. producing plants in Georgia and Tennessee.

WITHERITE

The Baroid Sales Division of the National Lead Co. mines a mixed witherite-barite near El Portal, Calif., and grinds the material without separation, mostly for oil-well drilling muds. The production of this mixture is reported as barite.

Northern England is virtually the world supplier of witherite, and modest quantities are imported into the United States from that source.

Witherite, crude, unground, imported for consumption in the United States, 1939–43

[Value at point of shipment]

Year	Short tons	Value	Year	Short tons	Value
1939	3,819	$64,106	1942	3,066	$60,824
1940	3,584	70,126	1943	448	9,452
1941	4,790	107,238			

According to Oil, Paint and Drug Reporter, witherite, 99 percent through 200-mesh, bags, carlots, works, was quoted at $43 a short ton in 1943.

BARIUM CHEMICALS

PRODUCTION

Statistics on the barium-chemicals industry are presented in the present chapter in considerably more detail than in the past. Heretofore only the quantity of barium chemicals sold for consumption outside the barium-chemicals industry has been reported. In the present chapter two new entries have been added, one showing production of barium chemicals, the other showing the quantities of barium chemicals used by the barium-chemicals industry in making other barium compounds.

Barium chemicals are used directly or indirectly for many war and essential civilian purposes. Lithopone was in heavy demand in 1943 and helped to relieve shortages of the more opaque titanium, zinc, and lead pigments. The shortage of drying oils has encouraged the use of lithopone in paints incorporating a synthetic resin binder.

Barium chloride is one of the principal barium salts. Besides being a source of other barium chemicals, it is used to purify salt brines for chlorine and sodium hydroxide manufacture, in the manufacture of coatings for photographic paper, as a flux in making magnesium alloys, and in finishing white leather.

Blanc fixe (precipitated barium sulfate) is used as a filler in white paint, rubber, linoleum, and other materials. Barium carbonate is used as a carbon carrier in case-hardening steel, in preventing efflorescence in structural bricks, and as a starting point in making other barium compounds, including the nitrate, oxide, peroxide, and hydroxide. The nitrate is used in green signal flares and explosives, the oxide in case-hardening steel, the peroxide in making hydrogen peroxide, and the hydroxide in beet-sugar purification and refining animal and vegetable oils.

Barium chemicals produced and used or sold by producers in the United States, 1941–43, in short tons

POST-WAR OUTLOOK

Many paint producers foresee a gloomy future for lithopone after the war because of the increasing availability of titanium pigments. On the other hand, wartime successes with the new lithopone water paints, which may be applied directly to wallpaper, may well carry over into peacetime.

Barite appears to have an assured post-war market in well drilling. No substitute has been found that equals barite in specific gravity, neutral effect on drilling mud, low cost, and ease of use.

If barite operations in Georgia and Tennessee continue to encounter increasing overburden, producers in Missouri may eventually find it possible to compete in eastern chemical and lithopone markets, despite the higher freight. Imports of German crude barite will probably be resumed, unless the $4 per ton duty is increased. In pre-war years imports totaled about 40,000 tons a year.

An interesting post-war possibility is the use of ground and floated Arkansas barite in making barium chemicals. In the past, lump barite, crushed to 4-mesh, has been used exclusively in making chemicals, for if ground material were reduced in the kiln, dust losses would be prohibitive. Strontium chemicals are made by digesting ground celestite (strontium sulfate) in a solution of soda ash, yielding the carbonate, and there seems to be no fundamental technological reason why barium carbonate could not be produced in the same manner. From the carbonate other barium chemicals could easily be produced.

GENERAL CONDITIONS

New records in production and sales of domestic potassium salts were made again in 1943. Nearly a million and a half tons of marketable potassium salts (1,428,840 short tons) containing 739,141 tons of equivalent potash (K_2O) were produced. (See fig. 1.) A somewhat smaller quantity (1,401,271 tons) was sold, which, according to reports from the producers, contained 732,151 tons of equivalent potash. Stocks of salts in producers' hands at the end of 1943 were larger than in any of the 3 previous years. Exports of both fertilizer potash and potash for chemical purposes were larger in 1943 than in 1942. Imports of potash for fertilizer use nearly tripled those in 1942, as a result of the delivery of considerable potash from the U. S. S. R. Domestic consumption of potash was about 680,000 short tons of K_2O—much the largest ever recorded.

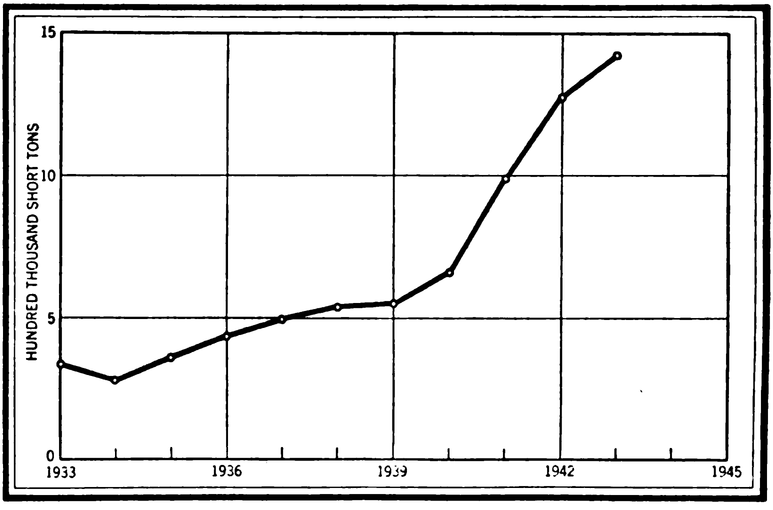

Figure 1.—Production of marketable potassium salts in the United States, 1933–43.

On June 9, 1943, Secretary of the Interior Harold L. Ickes issued an order (No. 1829) revoking the original order of 1935 restricting the granting of potash-development leases and authorizing the issuance of additional prospecting permits and leases for new potash development on the Public Domain when consistent with sound conservation policies and prevailing market conditions.

POST-WAR OUTLOOK

The present producing capacity of the domestic potash mines is more than enough to care for normal domestic requirements under peacetime conditions. Foreign competition will doubtless again be active, and the availability of foreign supplies will tend toward a decreasing demand for domestic potash in both the United States and foreign markets. However, exportation of food products to war-devastated countries may maintain production of potash at high levels for some time after hostilities cease.

General reviews of the potash industry in the war period by Turrentine[1] and Kieffer[2] and a discussion of fertilizers and fertilizer chemicals by Brand[3] appeared in 1943. A short statement (Document 17199) issued June 12, 1943, by the Office of Price Administration outlined the situation in the potash industry in stating the considerations involved in the issuance of Maximum Price Regulation 404—Potash.

DOMESTIC RESERVES

Domestic potash reserves comprise a variety of potassium-bearing minerals—sylvite, langbeinite, carnallite, polyhalite, alunite, leucite, greensand, sericite, and feldspar. To these should be added potash-bearing brines and cement-byproduct potash salts.

Sylvite, langbeinite, the brines, and cement-kiln flue dust only are being produced commercially. Alunite treatment has passed the pilot-plant stage, and commercial recovery of the potash content is expected shortly. The other potassium minerals constitute stand-by sources and await further technologic advances, development of marketable coproducts, depletion of the present productive deposits, or favorable economic changes before profitable production can be expected.

Sylvite, carnallite, and langbeinite have been found in an area of about 3,000 square miles in New Mexico and Texas. A smaller included area of some 100 square miles constitutes the New Mexico potash field. About 33 square miles of this smaller field contains beds of potash salts 4 feet or more thick which analyze at least 14 percent K_2O and contain 100,000,000 tons of potash salts, as estimated by the Geological Survey in 1933. One-fourth of these salts was estimated to contain over 28 percent K_2O. Later estimates, made about 1940 but before the intensive developments of recent years, placed the potash reserves of this area at 75,000,000 tons of equivalent K_2O. No current estimates are available, either of the total reserves or of the reserves of the individual potash salts recoverable at a profit under existing conditions.

The known high-grade potash salts of this district are now being consumed in large quantities, nearly 3½ million tons of crude sylvite and langbeinite (727,394 tons K_2O) being mined in 1943. The expectation of life of these reserves is being proportionately shortened. The average K_2O content of the crude sylvite mined annually is likewise becoming less; it has decreased from around 26 percent in the earlier years of mining in this district to 22.6 percent in 1943.

The potash-bearing brines now exploited at Searles Lake, Calif., were estimated to contain 10 to 12 million tons of K_2O in 1940. No estimates are available as to the currently productive shallow brines of the Salduro Marsh in Utah; but they are probably quite limited in extent, and little is known regarding the deeper brines.

Insufficient data are available for an estimation of the potash reserves of Grand County, Utah, where carnallite appears to be the most abundant potash salt but where sylvite and polyhalite also occur.

Reserves of alunite in the Marysvale district, Utah, are not definitely known. Reserves of alunitized rock were estimated by the Geological Survey in 1941 to total 36,921,000 tons, of which 10,324,600 are alunite. Only 1,361,000 tons are said to contain 50 percent or over of alunite. The Bureau of Mines gives somewhat larger figures.

Other potash-bearing minerals that may be utilized in the future include polyhalite, carnallite, leucite, greensand, sericite, and feldspar. Polyhalite is the most abundant and widely distributed potash mineral in the Permian Basin and is known to occur in minable thickness at several localities in New Mexico and Texas. Reserves are unknown but are probably large. Carnallite occurs both in the New Mexico and the Utah fields. Reserves are not known in either field. The leucite-bearing rocks of the Leucite Hills, Wyo., likewise a possible source of supply, have been estimated to contain nearly 200 million tons of potash. The potash-bearing silicate glauconite occurs in the greensand deposits of the Atlantic and Gulf coasts. The richest deposits are in New Jersey and Delaware and have been estimated to contain 257 million tons of K_2O. Sericite and feldspar are less important possible sources of potash.

PRODUCTION AND SALES

The annual increase in the production of marketable potassium salts in the United States since 1934 was in evidence once more in 1943, and again it was large; however, it was much less than the percentage increases in the last 2 years, being but 13 percent over 1942 compared with a 28-percent increase in 1942 over 1941 and a 50-percent increase in 1941 over 1940. The approximate equivalent K_2O content, however, was only 9 percent greater in 1943 than in 1942. Production in 1943 was 1,428,840 short tons, having an average K_2O content of 51.73 percent compared with 53.59 percent in 1942. Production of equivalent potash (K_2O) in 1943 exceeded that of 1942 by 59,935 tons. Sales of potassium salts were nearly a million and a half tons (1,401,271 tons) in 1943, a 10-percent increase over 1942. The contained equivalent potash (K_2O) was 732,151 tons, an increase of only 8 percent over 1942. Production exceeded sales in 1943, and producers' stocks were larger at the end of the year than at the beginning, increasing from the recent low point of 14,158 tons at the end of 1942 to 43,591 tons on December 31, 1943. The average value per ton of the potassium salts sold increased from $17.98 in 1942 to $18.69 in 1943. Production of all types of marketable potassium salts listed in the following table was larger in 1943 than in 1942.

Potassium salts produced in the United States, 1941–43, by grades, in short tons

Grade	1941	1942	1943
Muriate of potash: 60–62 percent K_2O minimum	663, 608	878, 997	934, 961
48–50 percent K_2O minimum	85, 398	85, 680	90, 137
Manure salts, run-of-mine	154, 979	183, 404	242, 189
Sulfate of potash and sulfate of potash-magnesia	82, 473	119, 374	152, 553
	986, 458	1, 267, 455	1, 428, 840

The western character of the domestic potash industry became still more pronounced in 1943 with the increased production of the Western States and the lessened output of the East. Virtually all (99.9 percent) of the 1943 output, in terms of K_2O, came from California, New Mexico, and Utah. About 82½ percent of the equivalent K_2O production in 1943 came from the deeply buried Permian saline sedimentary deposits of New Mexico and nearly 17½ percent from the saline lake brines of California and Utah, whereas less than 0.1 percent was recovered as a byproduct from manufacturing processes (cement and distillery operations in Maryland). The potash salts sold in 1943 were largely refined or processed products.

The potash-producing companies in the United States in 1943, by States, were as follows:

California:
- The American Potash & Chemical Corporation, 122 East 42d Street, New York City (plant at Trona, on Searles Lake, Calif.).

Maryland:
- North American Cement Corporation, 41 East 42d Street, New York City (plant at Security, Md.).
- U. S. Industrial Chemicals, Inc., 60 East 42d Street, New York City (plant at Baltimore, Md.).

New Mexico:
- International Minerals & Chemical Corporation, 20 North Wacker Drive, Chicago, Ill. (mine and plant near Carlsbad, N. Mex.).
- Potash Company of America, Carlsbad, N. Mex. (mine and plant near Carlsbad, N. Mex.).
- United States Potash Co., Inc., 30 Rockefeller Plaza, New York City (mine and plant near Carlsbad, N. Mex.).

Utah:
- Bonneville, Ltd., 540 West Seventh South, Salt Lake City, Utah (plant near Wendover, Utah).

Potassium salts produced, sold, and in producers' stocks in the United States, 1939–43

Year	Production			Sales				Producers' stocks

PRICES

Price lists for the 1943–44 fertilizer season were released by the major potash companies on dates ranging from April 7 to May 1, 1943, whereas in 1942 the release dates ranged from May 29 to June 15. Most of the schedules covered the 12 months from June 1, 1943, to May 31, 1944. The following base prices were reported by various producing companies:

Muriate of potash (62 to 63 percent K_2O, 62 percent K_2O minimum).	53½ cents per unit K_2O.
Muriate of potash (60 percent K_2O minimum)	53½ cents per unit K_2O.
Muriate of potash, granular (48 to 52 percent K_2O, 48 percent K_2O minimum).	56 cents per unit K_2O.
Muriate of potash, granular (50 percent K_2O minimum).	56 cents per unit K_2O.
Manure salts:	
22 to 26 percent K_2O, 22 percent K_2O minimum, run-of-mine.	20 cents per unit K_2O.
22 percent K_2O minimum	20 cents per unit K_2O.
Sulfate of potash (90 to 95 percent K_2SO_4, basis 90 percent K_2SO_4).	$36.25 per short ton.
Sulfate of potash-magnesia (basis 40 percent K_2SO_4, 18.50 percent MgO).	$26.00 per short ton.

Basing points for the New Mexico companies for muriate of potash were designated to be ex-vessel Atlantic and Gulf ports within the United States (ports designated by two of the companies), and for the American Potash & Chemical Corporation ex-vessel principal continental United States ports. Prices for manure salts, where stated, were based upon Carlsbad, N. Mex., only. Sulfate of potash and sulfate of potash-magnesia prices quoted by the International Minerals & Chemical Corporation were ex-vessel Atlantic and Gulf ports within the United States. At buyer's option muriate of potash could be purchased f. o. b. Carlsbad, N. Mex., at 11.2 cents per unit K_2O below ex-vessel price and f. o. b. Trona, Calif., for 8 cents per unit K_2O below net ex-vessel price at Pacific coast ports.

The split-discount system was continued. Seasonal discounts offered by the Potash Company of America, the International Minerals & Chemical Corporation, and the American Potash & Chemical Corporation were 8 percent from ex-vessel prices on orders accepted before July 1, 1943, for delivery (shipment in the case of the International company) in approximately equal monthly installments from June 1, 1943, through March 1944, and 4 percent additional upon completion of contracted deliveries. The United States Potash Co. allowed 8 percent discount from ex-vessel prices on orders placed for June delivery and on those placed before July 1, 1943, for equal monthly tonnage deliveries from June 1, 1943, to March 31, 1944, and 4 percent additional credit upon completion of contracted deliveries. On orders placed after June 30, 1943, and before October 1, 1943, for equal monthly tonnage deliveries October 1, 1943, to March 31, 1944, the International Minerals & Chemical Corporation and the United States Potash Co. allowed 4 percent discount from ex-vessel prices plus 2 percent additional upon completion of delivery (United States Potash Co.) and shipment (International) of the contracted tonnage. The Potash Company of America for this period offered only 2 percent discount from ex-vessel prices but allowed 4 percent on the completion of the delivery of the contracted tonnage. The American Potash & Chemical Corporation allowed no discounts after July 1, 1943; the three New Mexico companies allowed none after September 30, 1943. On manure salts the only two producers—the United States Potash Co. and the Potash Company of America—allowed the same percentage discounts as set forth for muriate of potash.

On June 12, 1943, the Office of Price Administration issued Maximum Price Regulation 404—Potash, effective June 18, 1943. This regulation covered muriate of potash, sulfate of potash, sulfate of potash-magnesia, and manure salts and placed under specific dollars-and-cents ceilings all sales of these salts by domestic producers of potash to fertilizer manufacturers. Maximum prices were also fixed on potash originating outside of the United States and imported into continental United States for sale and delivery to a fertilizer manufacturer within the United States and any of its Territories and possessions. Sales, purchases, and deliveries of imported potash, except to fertilizer manufacturers, were governed at that time by the provisions of the general maximum price regulation and by Revised Supplementary Regulation 12 (7 F. R. 10532; 8 F. R. 6111, 2035).

Second Revised Maximum Price Regulation 135, issued November

17, 1943, with an optional effective date on or after November 23, 1943, but not later than January 1, 1944, established dollars-and-cents maximum prices for every grade of mixed fertilizer, superphosphate, and potash, whose manufacture and sale are permitted by the War Food Administration.

CONSUMPTION

Consumption of potash salts in the United States and its possessions in 1943 was approximately 680,000 short tons of K_2O. The following table, based largely upon the deliveries of potash of domestic origin as reported by the American Potash Institute, would indicate actual sales for domestic consumption in the United States of 684,118 short tons. Apparent consumption, calculated by subtracting exports (70,007 tons) from the sum of the imports (17,109 tons) and producers' sales (732,151 tons), was 679,253 tons of K_2O in 1943.

Apparent domestic consumption of potassium salts, in terms of equivalent potash (K_2O) and its relationship to sales of domestic producers, as reported to the Bureau of Mines, for a period of years is shown in figure 2.

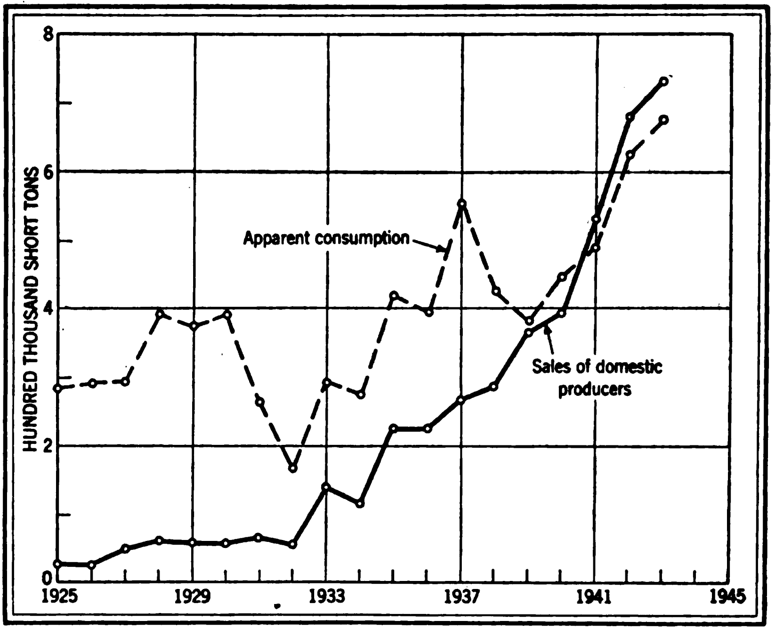

FIGURE 2.—Comparison of apparent domestic consumption of potash (K_2O) and sales by domestic producers of potash in the United States, 1925–43.

According to the figures of the American Potash Institute on potash deliveries, nearly 88 percent of the domestic deliveries of American potash in 1943 went to the fertilizer industry and a little over 12 percent for chemicals.

Sales of potash in the United States for consumption and export, 1941–43, in short tons of K_2O

	1941	1942	1943
Deliveries of primary potash of domestic origin by major companies, as from reports of American Potash Institute—			
In United States and possessions:			
Agricultural	435,940	558,356	591,210
Chemical	51,531	63,388	83,784
For export	24,807	38,504	47,907
	512,278	660,248	722,901
Imports for consumption plus sales of minor domestic producers	35,126	24,280	31,224
	547,404	684,528	754,125
Total exports (estimate by Bureau of Mines)	56,873	[1] 49,120	70,007
Actual sales for consumption in the United States	490,531	[1] 635,408	684,118

[1] Revised figures.

REVIEW BY STATES

General.—In 1943 merchantable potassium salts were produced in four States—California, Maryland, New Mexico, and Utah. The output of States (except for New Mexico, where there were three companies) cannot be given separately without disclosing individual company returns. New Mexico is by far the largest domestic producer, furnishing 84 percent of the total. California, although supplying much less than New Mexico, yields considerably more than the combined output of the other two States.

California.—The American Potash & Chemical Corporation (122 East 42d Street, New York City), only producer of potash in California in 1943, utilized the complex alkaline brine of Searles Lake in the southeastern part of the State as its potassium-bearing raw material and produced both agricultural and chemical grades of potassium chloride, as well as potassium sulfate. The brine is taken from a depth of 70 feet below the surface in wells and pumped 4 miles to the plant where[4] —

> After mixing with plant end liquors, it is sent to large triple-effect evaporators, concentrated, and separated into various salts, including borax, by carefully controlled fractional crystallization based on phase rule data. The solubilities of the carbonate, sulfate, and chloride of sodium being much lower, a large portion thereof is first precipitated and removed from the system. After further evaporation of the borax-potassium chloride-rich fraction, the potassium chloride is removed by rapid cooling under vacuum.

Maryland.—Two companies in Maryland produced byproduct potash for agricultural use in 1943. One of these producers—the Security plant of the North American Cement Corporation (41 East 42d Street, New York City), in Washington County, Md., a short distance east of Hagerstown—recovered several thousand tons of impure sulfate of potash from cement-kiln flue dust. In January 1943, U. S. Industrial

Fertilizer, vol. 199, No. 7, September 25, 1943, p. 11; abs. of paper presented before Am. Chem. Soc. meeting, Div. of Fertilizer Chemistry, Pittsburgh, Pa., September 6–10, 1943.

Chemicals, Inc. (60 East 42d Street, New York City), manufactured a small quantity of byproduct potash-bearing material by incinerating waste residue from its distillation of industrial alcohol from fermented molasses at its Fairfield plant, Baltimore, Md.; no potash was produced thereafter because grain was substituted for blackstrap molasses, which was no longer available as a raw material for alcohol production.

New Mexico.—Mine production of potash salts in the Carlsbad region of New Mexico continues to increase, attaining new records annually. In 1943 the three companies operating in this area mined 3,433,243 short tons of sylvinite and crude langbeinite combined, almost 400,000 tons more than in 1942, when 3,035,549 tons were taken out. The average equivalent K_2O content of the mined salts decreased from 21.52 percent in 1942 to 21.19 percent in 1943. The average equivalent K_2O content of the sylvinite mined was 23.9 percent in 1940, 22.9 in 1941, 22.7 in 1942, and 22.6 in 1943.

All three companies mined sylvite (potassium chloride), and one—the International Minerals & Chemical Corporation—also mined langbeinite (a potassium-magnesium sulfate). The greater part of the mined production was sylvite, most of which was processed to yield 60-percent or higher-grade K_2O muriate. The production of merchantable potash salts in New Mexico in 1943 was 1,203,126 short tons (84 percent of the total domestic production), with an equivalent K_2O content of 609.638 tons (nearly 82½ percent of the total production). Sales were 1,178,570 tons (84 percent of the United States total), with an equivalent K_2O content of 604,414 tons (83 percent of the domestic total), valued at $21,918,503. Muriate of potash was produced by all three companies. Potassium sulfate and potassium-magnesium sulfate (sulfate of potash-magnesia) were produced from crude langbeinite by the International Minerals & Chemical Corporation in the refinery at its mine near Carlsbad. Potassium sulfate also was produced by the Potash Company of America.

The magnesium chloride plant of the Defense Plant Corporation, adjacent to the refinery of the International Minerals & Chemical Corporation at its mine, was completed early in 1943, and operation started on June 15, 1943. This plant is operated, on a fee basis, by the International. Magnesium-chloride cell feed is produced for use in the magnesium-metal plant owned by the Defense Plant Corporation at Austin, Tex., operated also by the International. The raw material for the Carlsbad plant is a waste potassium-magnesium-bearing brine, containing about 16 percent magnesium chloride. The magnesium chloride is obtained by evaporation and selective crystallization. The dried product is shipped to the Austin plant.

Late in February 1944 the United States Department of the Interior obtained bids for drilling certain potash areas in New Mexico near Carlsbad to permit further exploration for potash resources and to determine the quantity and grade of the potash deposits near Government well No. 23 in the Potash Reserve set up in 1931. This well, drilled several years ago about 15 miles northeast of Carlsbad, in NW ¼ sec. 35, T. 20 S., R. 29 E., Eddy County, N. Mex., disclosed an 11-foot bed of sylvite and halite, 5 feet of which contains more than 30 percent K_2O, said[5] to compare favorably in content and thickness with salts then being mined in Eddy County. Drilling was started on the new wells by the Bureau of Mines in cooperation with the Geological Survey about March 1, 1944.

Utah.—Interest was well-maintained in Utah during 1943 in all three types of potash occurrences—potassium-bearing brines, hydrothermal deposits of the potassium sulfate alunite, and bedded deposits of the potassium chlorides carnallite and sylvite. Commercial production of the brines continued, the alunites were under development, and the bedded chlorides were prospected by core drilling.

In 1943 Bonneville, Ltd. (540 West 7th South, Salt Lake City), was producing potassium chloride from brine at its plant near Wendover, Tooele County, Utah, close to the Nevada line on the Western Pacific Railroad from Salt Lake City. The brine utilized comes from the thin, saturated, crystalline salt mass of the Salduro Marsh near the western edge of the former Lake Bonneville, in the Great Salt Lake Desert in northwestern Utah. Operations at this plant were started in 1938; production increased annually to 1942, but in 1943 it fell to a little below the 1941 figures.

Considerable interest was evident in 1943 in the alunite deposits of the Marysvale district, although a more favorable aluminum situation and a large supply of potassium sulfate from other sources might influence future developments. The Bureau of Mines conducted some exploration on the deposits during the year. Some alunite was mined by Kalunite, Inc., and several thousand tons were shipped to Salt Lake City for treatment by its sulfuric acid process. This material was stock-piled at the company plant there. According to report this plant, erected for the treatment of Marysvale alunite by the Kalunite process, was operated for the first time in September 1943. It has a daily capacity of 100 tons of alumina. Many difficulties in operation were experienced, and during the remainder of the year there were numerous shut-downs to make technical adjustments. As a consequence, no commercial potash was produced. A summary of the Kalunite process is included in an article by Fleischer.[6]

Prospecting was in progress in 1943 in the Grand County potash field of eastern Utah. Late in 1942 the Potash Company of America (Carlsbad, N. Mex.) entered into a prospecting agreement with the Utah Magnesium Corporation whereby the former was to drill a number of deep wells and to prospect the holdings of the latter company near Crescent Junction on which earlier in 1942 the Defense Plant Corporation Reeder No. 1 well was drilled by the Bureau of Mines in cooperation with the Geological Survey.[7] The drilling operations in 1943 are reported to have been financed by the Potash Company of America. Drilling was started early in 1943, and four core holes are said to have been put down in this area during the year to depths of around 5,000 feet within a radius of about a mile of the Crescent Eagle well. No descriptions of the cores have yet been published. A paper[8] describing the earlier potash-bearing wells was presented at the New York meeting of the American Institute of Mining and Metallurgical Engineers in February 1944.

[7] Bureau of Mines, Thompson Magnesium Well, Grand County, Utah: War Minerals Rept. 12, 1942, 39 pp., 6 figs.

In September 1943 core drilling was reported to have been started about 2 miles east of Castle Dale, Utah, for the Dome Minerals Petroleum Co., of Salt Lake City, Utah, in a search for workable carnallite deposits.[9]

FOREIGN TRADE[10]

Imports.—As a result of current World War activities, imports of potash salts have shrunk from the several hundred thousand tons imported annually in pre-war years to a few thousand tons a year. In 1943, because of Lend-Lease imports of U. S. S. R. muriate of potash and larger receipts of Chilean potassium-sodium nitrate, imports of potassium salts more than doubled those in 1942, reaching 45,428 short tons estimated to contain 17,109 tons of K_2O. The total value of the imports, however, was much less because of greatly decreased imports of the high-valued argols.

Potash (K_2O) for fertilizer use constituted 67 percent of the total imports in 1942, whereas in 1943 fertilizer salts increased to over 99 percent of the total. Imports for chemical use dropped from 33 percent in 1942 to less than 1 percent of the total in 1943.

Potassium chloride (muriate) was the principal potash salt imported in 1943 for fertilizer use—25,212 tons out of the total of 45,009 tons. Virtually all of it came from the U. S. S. R. Imports of potassium-bearing materials for consumption in the chemical industries consisted principally of potassium bitartrate as argols and cream of tartar.

The stocks of the American Potash & Chemical Corporation and the Pioneer Potash Co. remain vested in the hands of the Alien Property Custodian (see Minerals Yearbook, 1942, pp. 1452–1453 and 1456).

[1] Approximate equivalent as potash (K_2O)—1942: 47 percent; 1943: 55 percent.
[2] Less than 1 ton.
[3] United Kingdom of Great Britain and Northern Ireland.

Exports.—The total export trade in potash materials in 1943 was valued at over 7 million dollars. The total fertilizer potash materials exported in 1943—111,541 short tons, the largest quantity since 1939—had a value of a little more than 3 million dollars. The fertilizer exports went largely to Canada (74,698 tons) and the United Kingdom (26,591 tons). Exports of chemical potash totaled 20,133 tons in 1943 and had a value of nearly 4 million dollars. The principal potash chemicals exported were the hydroxide (caustic potash), the nitrate and mixtures, the chlorate and mixtures, and the bichromate and chromate. United Kingdom, U. S. S. R., and Canada, in the order named, were the leading recipients of exported domestic potash chemicals in 1943.

WORLD PRODUCTION

Four nations continue to dominate world potash trade—Germany, United States, U. S. S. R., and Spain. Germany, the dominant producer of western Europe as well as of the world, retains the French and Polish potash industries, although early in 1944 the advancing Russian armies threatened its control of the potash deposits of Poland; it still holds all the important potash deposits of western Europe except those of Spain. Soviet Russia, with its large reserves in the Solikamsk region, controls the potash industry of eastern Europe. The United States is by far the largest potash producer in the Western Hemisphere; it is probably the second-largest producer in the world. Transportation along two of the potash trade routes—the Mediterranean and the Atlantic route from Murmansk—was eased for Allied movements by war developments.

World production of potash minerals and equivalent K_2O, 1938–43, by countries, in metric tons [1]

World production	1525

SUMMARY

Production of all kinds of mica and consumption of splittings and built-up mica reached an all-time high in 1943 as the industry expanded to meet the requirements of the armed services. Domestic production in 1943 supplied 11 percent of all receipts of good-stained and better compared with 10 percent for 1942. Although the percentage increase is small, the quantity produced is large because the total supply was much greater in 1943 than in the previous year.

India and Madagascar remain the chief producers, respectively, of muscovite and phlogopite splittings. Minor quantities of muscovite splittings were produced mechanically in the United States, and phlogopite splittings were also received from Canada and Mexico. A shortage of No. 5 or larger book-form muscovite splittings developed near the end of 1943 because of reduced production in India and restricted shipping space therefrom.

Since December 1942 the Metals Reserve Co., a subsidiary of the Reconstruction Finance Corporation, through its agent, the Colonial Mica Corporation, has been designated the sole purchaser of all strategic-grade domestic and imported Canadian mica. The mica section of the War Production Board allocates this mica to consumers, who make their purchases from the Colonial Mica Corporation. Much has been accomplished by these agencies. The number of mines operating at the end of 1943 was approximately 635 compared with 300 at the beginning of the year. Production has been increased, substitution of larger amounts of stained for clear mica has been made, and satisfactory electrical equipment to test the power factor and the presence of conducting veins or spots in mica was developed to supplement visual tests. A critical review of accomplishments has been presented in the Truman Committee Report.[1]

The accompanying table of salient statistics gives a summary of domestic production and consumption of mica during the past 5 years.

Value	$226, 364	$191, 550	$280, 810	$303, 526	$653, 889

---

[1] Includes mica recovered from kaolin and mica schists, as follows: 1939, 10,011 tons, $108,899; 1940, 9,674 tons, $138,148; 1941, 15,583 tons, $185,486; 1942, 20,481 tons, $315,807; 1943, 24,113 tons, $314,851.

DOMESTIC PRODUCTION

Sheet mica.—Production reached an all-time high in 1943—3,448,199 pounds valued at $3,228,742 compared with 2,761,844 pounds valued at $725,030 in 1942. Punch mica supplied 78 percent of this total or 2,691,083 pounds valued at $473,955; an increase over the 2,425,645 pounds of punch valued at $282,900 produced in 1942 but a decrease in percentage, as punch represented 88 percent of the total sheet produced in that year.

North Carolina remained the largest producer in the United States, supplying 57 percent of the total punch and 47 percent of the larger sheet in 1943. This is a decrease in percentage compared with 1942, when North Carolina furnished 60 and 61 percent, respectively, of the total output of punch and sheet mica; it is attributed to increased production in other States, notably New Hampshire, Georgia, Maine, and Idaho.

South Dakota was the third largest producer of mica; and although the quantity produced in 1943 declined from the 1942 total, the quality increased considerably. Georgia ranked fourth in 1943, displacing Connecticut. Before 1943 the production of mica in Georgia had been so small that the figures were not recorded separately. Maine attained sixth place, and substantial quantities were also received from Alabama, New Mexico, Idaho, Massachusetts, and Virginia.

[1] Includes small quantities of splittings in certain years.

[2] 1942: Alabama, California, Colorado, Georgia, Idaho, Maine, Massachusetts, New Mexico, South Carolina, Texas, Vermont, and Virginia. 1943: Alabama, Arizona, California, Colorado, Idaho, Maine, Maryland, Massachusetts, Montana, Nevada, New Mexico, Pennsylvania, South Carolina, Texas, Virginia, and Wyoming.

The increase in the quantity and value of sheet mica produced in 1943 and the decrease in the percentage of punch compared with the previous year may be attributed largely to the Government program of paying premium prices for three-quarter and full-trim mica. Monthly statistics of purchases of clear and stained mica were first collected by the Bureau of Mines in 1941 and may be used as an index of production, as it is impractical to canvass the multitude of small producers upon a monthly basis. Some divergence may be expected because of variations in stocks held by producers. The average monthly purchases of clear and stained mica, by quarters, for 1942 and 1943 are shown in figure 1.

The large increase in the production of stained mica in 1943 is attributed to the War Production Board program of substituting larger quantities of lower-grade material for clear mica wherever possible.

Scrap mica.—Production of scrap mica in 1943 increased to 46,138 short tons valued at $738,025 compared with 43,262 tons valued at $671,165 in 1942. In addition to mine scrap, these figures include 24,113 tons valued at $314,851, obtained from washing kaolin and by milling mica schists. Comparable figures for 1942 were 20,481 tons valued at $315,807.

Ground mica.—Production of ground mica in 1943 reached an all-time high of 51,582 short tons valued at $1,990,144 compared with 46,979 tons valued at $1,653,358 in 1942.

Present uses reflect the heavy demands for military applications and the weaker market in normal peacetime industry. Thus sales of ground mica used in paints for waterproofing tents and tarpaulins, in plastics, rubber, and welding-rod coatings increased, but those of dry-ground mica for roofing and wet-ground material used in wallpaper decreased. For pipe-line enamel use, fine, dry-ground mica is mixed

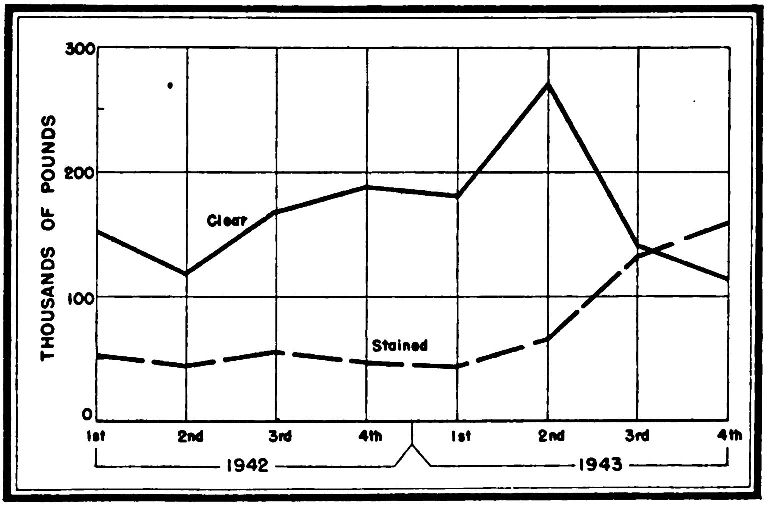

FIGURE 1.—Average monthly purchases of domestic sheet mica, clear and stained, for each quarter, 1942–43.

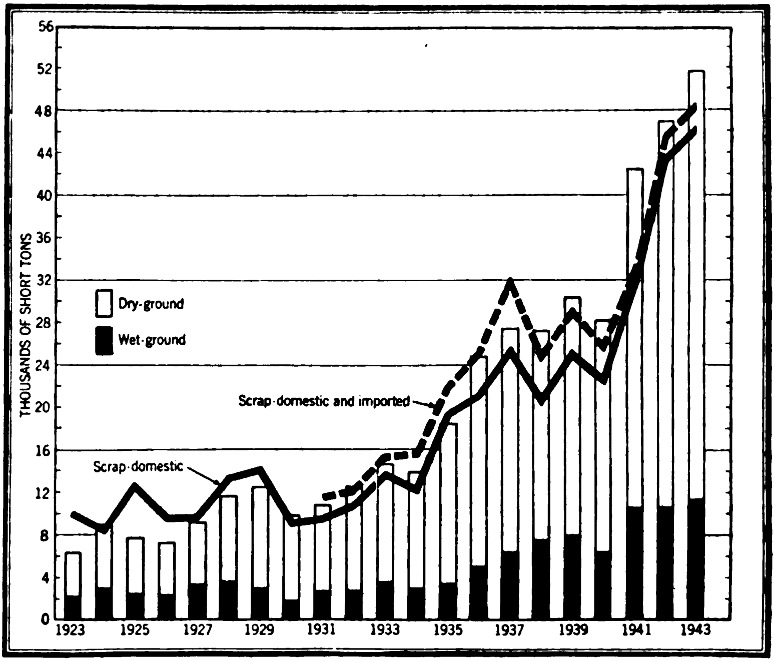

FIGURE 2.—Scrap and ground mica sold in the United States, 1923–43.

with a tar base. The flat mica plates serve as a binder in the enamel as well as an insulation medium.

The history of the scrap- and ground-mica industries over a series of years is indicated in figure 2.

TOTAL CONSUMPTION OF BLOCK AND SHEET MICA

Uses of the various grades of strategic mica in 1943 changed materially from the previous year. Radio, radar, and magneto condensers consumed more high-quality mica than the total military requirements for mica in the first half of 1942. Conservation and substitution programs developed in the laboratories of the armed services and the radio manufacturers made possible during the year the use of increasing amounts of stained mica in radio tubes, spark plugs, and applications where its function is primarily insulation and protection against flash-over rather than capacitance and high dielectric strength. Paper, ceramic products, and newly developed dielectric materials also proved satisfactory substitutes for some of the uses in which high-quality condenser-grade mica had previously been specified.

Figure 3 summarizes graphically the situation with respect to imports and domestic production. As reported by the Mica-Graphite Division of the War Production Board, approximately 94 percent of the total quantity of "good-stained and better" grades was used in military radio condensers and magnetos, and 93 percent of that classed as "stained" was used in radio tubes, condensers, and spark plugs. Stocks of the strategic grades on hand December 31, 1943, were adequate for 15 months' supply at the average rate of consumption during 1943. A break-down by sizes and grades shows that the supply of individual sizes ranges from 3 to 8 months for No. 5½ to 8 to 20 months for No. 6.

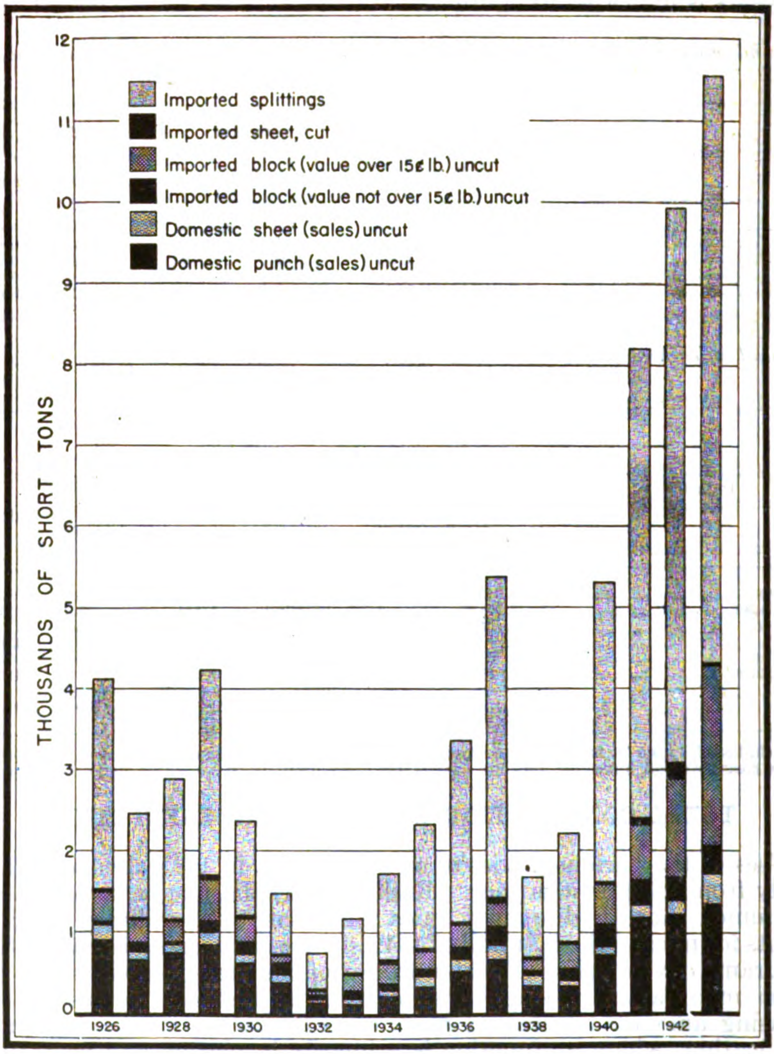

Figure 3.—Block and sheet mica (cut) and splittings imported for consumption in the United States and sales of domestic sheet and punch mica, 1926–43.

MICA SPLITTINGS

Consumption of splittings reached an all-time high in 1943; and, although Government stocks increased from 11,338,000 pounds on January 1, 1943, to 17,182,000 pounds by the end of the year, industry stocks decreased. A shortage developed in the supply of No. 5 or larger book-form muscovite splittings (which are used largely in the manufacture of tape for armature insulation in high-voltage generators, industrial motors and small transformers), and they were put under allocation control by the War Production Board in Order M 101–a, effective March 15, 1944. Consumption of muscovite splittings alone increased in each quarter. Amber splittings declined in the second quarter and then increased through the third and fourth quarters to a new high by the end of the year.

Grade 6 loose splittings—first-, second-, and third-quality—in 1943, as in the previous year, constituted 81 percent of the total consumption of muscovite splittings. Nearly equal amounts of first- and third-quality splittings were consumed, but consumption of No. 2 quality was greater than that of Nos. 1 and 3.

Consumption and stocks of mica splittings in the United States, 1939–43, by sources, as reported by the consumers

The phlogopite splittings manufactured in the Western Hemisphere in 1943 and imported by the United States came from material mined in Canada and Mexico. Mexican splittings were hand-split, but the Canadian splittings consisted of hand- and machine-split material. Splittings manufactured domestically consisted of machine-split phlogopite from Canada.

India is the sole large-scale producer of muscovite splittings, owing to its large supplies of mica and the necessary low-wage labor. Some block mica produced in Brazil is shipped to India for splitting.

The 1943 supply, except for No. 5 book-form muscovite splittings, was more than enough to meet requirements for the year. Consumption of splittings from July 1942 through December 1943 is summarized graphically upon a quarterly basis in figure 4.

BUILT-UP MICA

The consumption of all types of built-up mica products in 1943 increased 11 percent over the 1942 figures and reached an all-time high as the requirements of the armed services for commutator segments and V-rings for use in generators and starters and tape for armature insulation in high-voltage generators, industrial motors, and small transformers continued to increase. Increases of particular types ranged from 5 percent for "all other (tape, etc.)" to 17 percent for segment plate. Splittings used for built-up mica are mainly muscovite, but some phlogopite (amber) splittings are used in commutator segments in flush-type commutators.

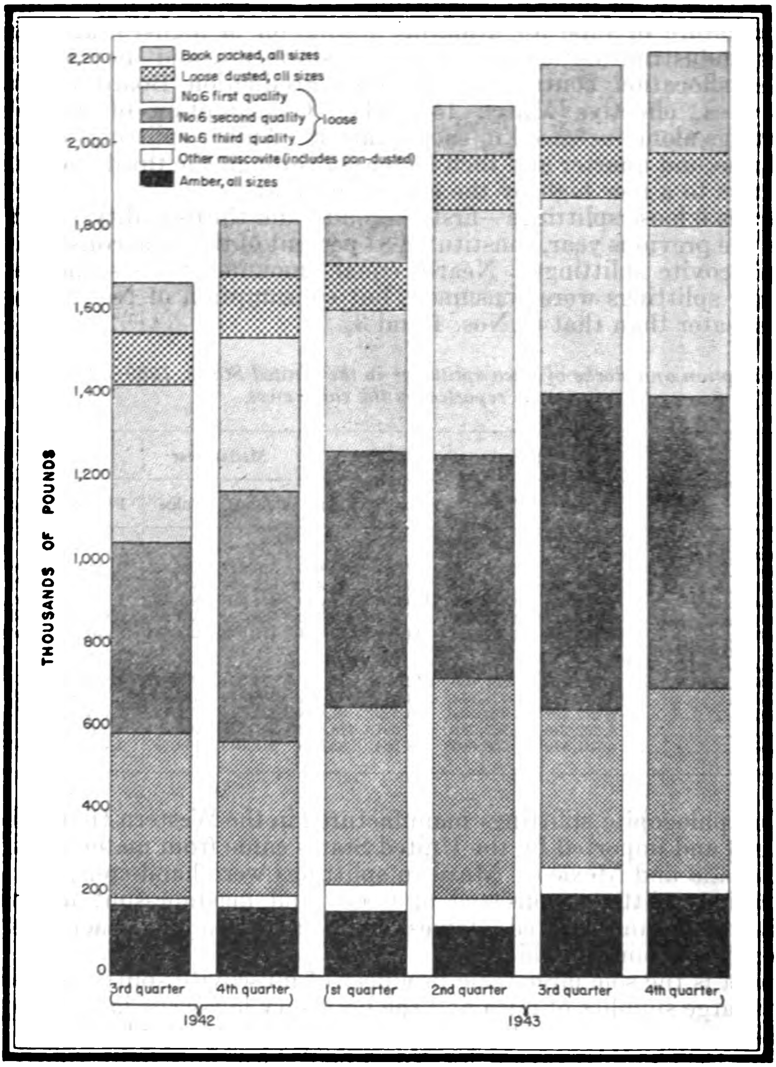

FIGURE 4.—Consumption of specified sizes and qualities of mica splittings in the United States, by quarters, July 1942 to December 1943.

Built-up mica produced in the United States, 1942–43, by kind of product[1]

Product	1942		1943	
	Pounds	Value	Pounds	Value
Molding plate	1,599,000	$1,552,000	1,785,000	$1,912,000
Segment plate	2,045,000	2,367,000	2,388,000	2,846,000
Heater plate	212,000	303,000	235,000	462,000

All other (tape, etc.)	1,628,000	2,794,000	1,716,000	3,222,000
	6,133,000	7,759,000	6,831,000	9,273,000

[1] Partly estimated.

PRICES

The requirements of the armed services for the smaller sizes of strategic mica increased greatly in 1943. After a careful study of requirements, prices, mine production, and costs, a new buying schedule that provided a substantially higher price to domestic miners for the smaller sizes and punch mica was released by the Colonial Mica Corporation on May 24, 1943, effective to December 31, 1943. The new schedule offers a fixed price for all sizes of sheet mica from 1½ to 2 inches and up of $5 per pound, provided the mica is three-quarter trim or better. Two alternatives are offered for the sale of punch mica:

(1) As punch mica, having a usable area less than 1½ by 2 inches, at a base price of 40 cents per pound.

(2) Sizes 1 by 1 inch up to 1½ by 2 inches full trim, $5 per pound for either No. 1 or No. 2 quality. On December 7, 1943, the effective date of this schedule was continued to June 30, 1944, and on January 28, 1944, it was further extended to December 31, 1944, and a bonus of $1 per pound was offered for all domestic strategic mica delivered to the purchasing shops of the Colonial Mica Corporation on or before June 30, 1944. Later this bonus also was extended to December 31, 1944.

The average selling price of the domestic mica sold to fabricators by the Colonial Mica Corporation is approximately $1.50 per pound, which is also the approximate average selling price of imported mica. The average cost of all the imported mica obtained by the Metals Reserve Co., however, is less than $1 per pound.

There is also a critical need for domestic nonstrategic sheet and scrap mica, which is produced at the same mines as the strategic material and in much larger quantity. However, although strategic grades were excepted from price control under Supplementary Regulation 1 to the General Maximum Price Regulation, the prices for nonstrategic grades were frozen at the March 1942 level. As the production costs of both grades are virtually the same, the effect was to restrict output of the lower-grade material. Therefore on March 26, 1943, the Office of Price Administration, under Order M. P. R. 347, removed nonstrategic punch, sheet and scrap mica and crude mica schist from price control. The maximum price of domestic ground mica, mica schist, water-washed mica, and micronized mica was raised $5 per ton for all producers except David T. Vance of Plumtree, N. C., and the Newdale Mica Co. of Erwin, Tenn., who were allowed an advance of $10 per ton. On June 21, 1943, under Amendment 2 to M. P. R. 347, a ceiling of $25 per ton was placed on scrap, byproduct scrap, jig scrap, or other scrap produced in Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, or New York, f. o. b. mine or rifting shop.

Trade-journal quotations and average sales value of domestic uncut sheet mica per pound in 1943

Size	Trade-journal quotations [1]		Average value [2]	
	Clear	Black-stained	Clear	Stained
Punch	$0.30	$0.12	$0.233	$0.064
1 by 1 inch			1.213	.368

[1] E&MJ Metal and Mineral Markets quotations for minimum half trim.
[2] Calculated from reports of sales by domestic producers to the Bureau of Mines.

POST-WAR OUTLOOK

The post-war problems of the domestic mica industry will be chiefly economic. Production statistics for 1942 and 1943 show that domestic mica mines can produce, on the average, as high a percentage of good-stained and better grades of mica as either Indian or Brazilian mines, but trimming costs alone—disregarding mining costs—exceed the cost of importing Indian or Brazilian material tariff included.

The two mica-testing instruments developed by the Bell Telephone Laboratories to measure dielectric quality (power factor) and to indicate the presence of conducting mineral inclusions or pinholes have made possible the use of large quantities of stained material for condenser purposes. However, the domestic industry will not benefit appreciably from the use of this equipment until the large stocks of imported stained material on hand have been consumed.

The premium price of $6 per pound now paid by the Colonial Mica Corporation is established only for the duration of the war, unless favorable action is taken on the proposal made by the War Production Board to continue this price for the additional time thereafter required to create a Government stock pile sufficient for 3 years. Peacetime costs of producing sheet mica in the United States are estimated at approximately $3 per pound compared with $1.11 and 92 cents per pound for Indian and Brazilian mica, respectively, of comparable grade. It does not seem probable therefore that the post-war markets for domestic mica will be larger than during the years immediately preceding the war.

FOREIGN TRADE[2]

Imports.—In 1943 imports of all kinds of mica totaled 13,759 short tons valued at $14,854,066 compared with 11,294 tons valued at $9,027,778 in 1942. Imports of block mica, films, and splittings increased, but those of ground mica decreased; no imports were received of manufactured products in which mica is the component of chief value.

---

[2] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the United States Department of Commerce.

The increased value of imports in 1943 may be attributed mainly to the larger quantities of higher-grade sheet mica and the larger sizes of films and splittings received. Large-size films and splittings are valued at $1 to $1.25 per pound compared with 65 cents per pound for the smaller sizes. Another factor was that the greater part of the ground or pulverized mica imported was wet-ground material valued at $30 to $60 per ton compared with $16 per ton for the dry-ground material received in 1942. Further details on imports, by kinds and sources of origin, may be found in the following tables.

Exports.—Exports of both unmanufactured and manufactured mica were lower in 1943 than 1942. The unmanufactured mica exported to Mexico consists chiefly of Indian and Brazilian block mica reexported for manufacture into condenser splits, all of which are returned to the United States.

MICA AVAILABLE TO ENEMY COUNTRIES

Complete answers to the question of the quantity and quality of the mica available to the enemy countries cannot be given until after the war; however, some estimates may be made.

Their preparation for war began years before ours, and large stock piles were accumulated. Germany, Italy, and Japan imported heavily from India, Argentina, and Brazil. Exports of mica from India to Japan were not shut off until July 1941 and from Brazil and Argentina to Japan, Italy, and Germany until January 1942. A large part of the Japanese imports of mica was purchased for the account of Italy and Germany. Also from captured equipment it is known that their electronic program was designed with a mica shortage in mind.

The sources of supply of mica to Germany in 1943 and estimates of the quantity and quality available, as reported by the Foreign Economic Administration and consular reports, are as follows:

	Short tons	*Sheet mica, percent*
Rumania	551	4. 8
Norway	220	1. 2–4. 8
Bulgaria	220	2. 2–4. 8
Spain	167	100. 0
Macedonia	7	30. 0 70. 0 splittings

Little is known of the sources of mica now available to Japan. It seems probable, however, that except for domestic production, most of which is scrap, it controls only the mica in Chosen (Korea), the major part of which is phlogopite.[3] Japan bought all grades of mica from Argentina, Brazil, and India, in contrast with Germany and Italy, which purchased only sheet mica. The annual output of the Peruvian mimes—approximately 200 tons, the greater part of which was scrap—was also purchased by Japan until December 7, 1941.

WORLD PRODUCTION

Data on foreign production are not complete at this time, but reports from the major producing countries and some new sources show an increase in output of the better grades of muscovite and phlogopite mica. The following table presents available figures by countries from 1938 to 1943.

[1] In addition to the countries listed mica is also produced in Chosen, Colombia, Eritrea, Kenya, Portugal, and U. S. S. R., but data on production are not available.
[2] Data not available.
[3] Exports.
[4] Includes following quantities recovered from kaolin and schists: 1938, 5,942 tons; 1939, 9,082 tons; 1940, 8,776 tons; 1941, 14,137 tons; 1942, 18,580 tons; 1943, 21,875 tons.
[5] Rail and river shipments.
[6] Estimate.
[7] Less than 1 ton.
[8] July to December, inclusive.
[9] January to September, inclusive.

Argentina.—The Argentine became our third largest foreign source of strategic mica in 1943, providing 11 percent of our supply or an amount approximately equal to domestic production. All purchases from Argentina were for private account as no Government agency entered actively into either purchasing or mining.

Brazil.—The United States Purchasing Commission has been responsible for Brazilian mica production since July 1942, providing technical assistance, renting mining equipment, and operating some mines under contract with the owner. Under this stimulus Brazilian mica production increased and in 1943 accounted for approximately 18 percent of the United States supply of good-stained and better grades of mica.

Canada.—Production of sheet muscovite, phlogopite splittings, and ground mica continued to increase during 1943. Additional deposits of muscovite were opened in the Eau Claire district of Ontario.

India.—India maintained its place as the dominant world supplier of strategic mica in 1943. The threat of Japanese invasion eased, and the transport problem was solved by airborne shipments of strategic grades to the United States and the United Kingdom.

Madagascar.—Small shipments of phlogopite block and splittings were received from Madagascar in 1943, and larger quantities are expected in 1944, as production, aided by additional mining equipment, has increased.

SALT

World production	1539

SUMMARY

The mines, wells, and ponds in the United States yielded 15,214,152 short tons of salt valued at $43,878,266 in 1943, representing increases of 11 percent in quantity and 15 percent in value over the 1942 totals. The unit value increased from $2.79 to $2.88. Of the 1943 output, brine increased 8 percent, rock salt 16, and evaporated salt 14 percent.

Increases were due primarily to war requirements of magnesium metal, synthetic rubber, and rubberlike materials, for which all classes of salt were used. Exports of salt increased 23 percent, chiefly in shipments to Newfoundland and Labrador, Canada, Mexico, and Greenland. Imports of salt (which decreased 84 percent) included no shipments of salt for curing fish, an unusual situation.

Salient statistics of the salt industry in the United States, 1935–39 (average) and 1940–43

	1935-39 (average)	1940	1941	1942	1943
Sold or used by producers:					
Manufactured (evaporated) short tons	2,507,374	2,782,741	3,330,106	3,517,832	3,993,899

---

[1] Values are f. o. b. mine or refinery and do not include cost of cooperage or containers.

[2] Includes salt in bags, sacks, barrels, or other packages—1938: 93 tons valued at $673; 1940: 6 tons, $12; 1942: 122 tons, $1,200.

[3] Quantity sold or used by producers plus imports minus exports.

The acute shortage of labor and the large turn-over hampered operations and reduced the output in many salt fields and plants. Some of the smaller companies closed for the duration of the war or until the labor situation improves. No strikes were reported. The only sections of the country reporting poor demand are those that serve small local markets chiefly with cattle salt and are unfavorably located with respect to markets and railroad facilities. Many sections experienced difficulty in moving the salt, as transportation facilities were lacking. Certain salt fields in the path of Army maneuvers were inactive in 1943. Two Defense Plant Corporation plants began producing salt in 1943. Several magnesium-metal manufacturers expanded operations, which increased salt requirements greatly, but as the new units were not in full operation until well into 1943 the entire increase is not yet reflected in totals reported.

The accompanying graph (fig. 1) is not comparable with corresponding charts in the Salt chapters of Minerals Yearbook, 1941, and previous years because the Federal Reserve Board index of industrial production has been revised. (See Federal Reserve Bulletin, October 1943, pp. 940–952.)

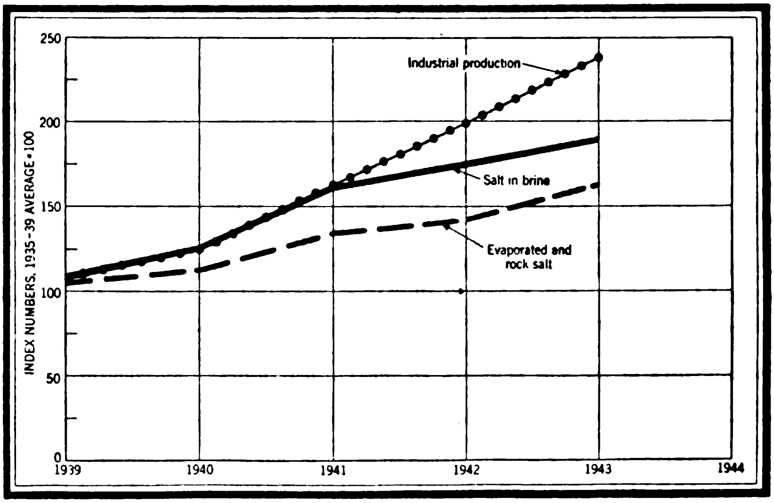

FIGURE 1.—Index of salt in brine and of evaporated and rock salt compared with industrial production, 1939–43. Index of industrial production from Federal Reserve Board.

PRODUCTION

Salt was produced by 57 companies in 83 plants operating in 13 States and Puerto Rico in 1943 compared with 64 companies operating 86 plants in 14 States and Puerto Rico in 1942.

Production of the three classes of salt is compared in the accompanying graph (fig. 2).

Production by States.—The order of magnitude of production of salt of all classes by the leading States was as follows: Michigan, New York, Ohio, Louisiana, Texas, Kansas, and California.

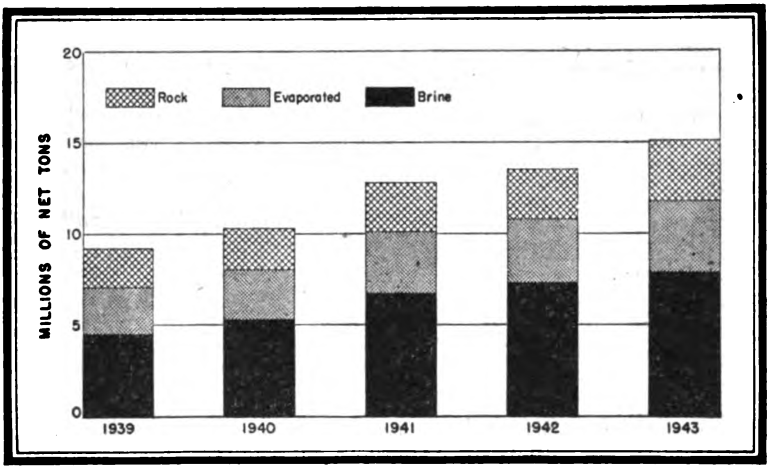

FIGURE 2.—Trends in the quantity of rock salt, evaporated salt, and brine (in terms of salt content) sold or used by producers in the United States, 1939–43.

Salt sold or used by producers in the United States, 1941–43, by States

[1] Less than 0.5 percent.
[2] 1941: Colorado and Virginia; 1942: Colorado, Nevada, and Virginia; 1943: Nevada and Virginia.

All seven plants in Puerto Rico produced table salt. Demand on the island was good throughout 1943.. However, the producers were handicapped by the heavy rainfall during the production period and the hurricane of October 14, which lowered the output as a great deal of salt was dissolved, the ponds overflowed, and mud and other impurities were carried into the pans. It has been reported that sales since December 1943 were rationed because of the ensuing salt shortage.

Methods of manufacture.—Various methods of salt manufacture are employed, and the quantities made by each method are given in the accompanying table. The quantities produced in open pans and grainers are combined, including also a considerable quantity produced by the Alberger method.

Salt sold or used by producers in the United States, 1942–43, by methods of manufacture

Method of manufacture	1942		1943	
	Short tons	Value	Short tons	Value
Evaporated:				
Bulk:				
Open pans or grainers	500,758	$4,607,104	532,747	$5,083,816

	3,517,832	22,990,271	3,993,899	26,731,005

[1] Includes a quantity of salt contained in brine for chemical use reported as evaporated salt with value as evaporated salt.

[2] Included under "Other States."

[3] 1942: Colorado, Nevada, and New Mexico; 1943: Nevada, New Mexico, and Texas.

Rock salt.—Twenty plants produced rock salt in eight States. For many years four States produced more than 90 percent of the national total. Because of the small number of producers of rock salt and salt in brine in certain States, it is impossible to show either rock salt or salt in brine separately, by States, if State totals for all classes of salt are published. Therefore, only annual totals are shown in the following table.

Rock salt sold by producers in the United States, 1939–43

Year	Short tons	Value	Year	Short tons	Value
1939	2,035,157	$6,496,807	1942	2,802,287	$9,623,461
1940	2,265,548	7,384,839	1943	3,259,138	11,180,884
1941	2,619,087	8,761,827			

Pressed blocks.—Salt blocks sold in 1943 showed a gain of 13 percent in quantity and 17 percent in value compared with 1942. Twenty plants produced blocks from evaporated salt, and 8 produced blocks from rock salt. The output consisted of plain, iodized, and sulfurized salt blocks.

Pressed-salt blocks sold by original producers of the salt in the United States, 1939–43

Year	From evaporated salt		From rock salt		Total

Salt content of brine.—Eleven plants in seven States produced 7,961,115 short tons of salt in brine in 1943, or 52 percent of the national total of all types of salt. The brine supplies salt needed for a substantial part of the chemical industry of the country, as salt tops the list of raw materials used in the chlorine and alkali industries and is utilized for many other chemicals. The increased use of salt in brine parallels the remarkable growth of the chemical industries. For quite a number of years the United States has led the world in these industries; and at the beginning of World War II, according to Falk,[1] it already supplied two-fifths of the world chemical production.

MODERN PRACTICES

Although many improvements in details have been evolved, no great basic changes have occurred recently in the United States in methods of producing salt from mines, wells, ponds, and playas.

Descriptions have been given recently of the Retsof (New York) and other mines of the International Salt Co.,[2] the Jefferson Island Salt Co. mine and works (Louisiana) rebuilt in 1941,[3] and the Kleer Salt mine (Kansas).[4] The Retsof mine operates in beds more than 1,000 feet below the surface, and the Detroit mine (Michigan) is more than 1,100 feet deep.

Of the three main mechanical methods of evaporating salt from brine—vacuum pan, open pans, and grainers (or by the Alberger modified open-pan method)—the vacuum-pan process requires the most costly equipment consisting of a complicated system of tubing, pans, and other equipment made of noncorrosive metals. As the metals and equipment required are the same as those used on battleships and other Navy craft, replacements and extensions of vacuum-process salt plants have been under strict priority control for the last few years. All three methods employed at the Diamond Crystal salt plant in Michigan were described in an article several years ago.[5]

Evaporation by solar heat and the harvesting methods practiced on the Pacific coast and at Great Salt Lake have been described in previous Yearbook chapters, but a unique experiment in solar evaporation is being tested at an inland sea in Mexico.[6] Ponds constructed spirally are so arranged that it takes 1 year for the brine to reach the center of the spiral, from which it goes to the crystallizers where complete evaporation is attained. Other salts in addition to sodium chloride are obtained.

Since iodized salt first came on the market in Michigan in 1924, production has increased steadily, and markets have expanded to national proportions. At present about half of the table salt produced is iodized.

Although salt must be in solution for utilization in some processes—notably magnesium-metal manufacture—users have found it economical of time, labor, and equipment to purify the salt first by the vacuum-pan method and later to redissolve it because the impurities contained in the unrefined brine clog the process or otherwise are deleterious.

C. D. Looker's article (cited in footnote 2) contains a useful table for testing sodium chloride brines.

Some of the wells in the United States yielding brine for the production of chemicals and evaporated salt penetrate the salt beds several thousand feet below the surface. The deepest on record is the 6,000-foot well of the Defense Plant Corporation that began large-scale operation at Natrium, W. Va., in 1943, to supply salt brine from which liquid chlorine and caustic soda are produced. The West Virginia location was chosen as it is above an extensive salt deposit, and fuel (coal and gas) and electric power are available nearby. It is adjacent to large markets and has both water and rail transportation.

DISTRIBUTION

The accompanying table shows movement of original shipments of evaporated and rock salt into the various States but not reshipments. Although some of the large salt companies maintain transshipment warehouses, the following table gives a valid pattern of distribution, as salt is such a cheap commodity at its point of origin that it cannot be sent too far afield or heavy freight costs make its selling price too high to compete with products located more favorably.

---

[1] Includes salt used in Puerto Rico (evaporated salt); exports to Africa, Canada, Central America, Cuba, Mexico, Newfoundland, South America, West Indies, and other countries; shipments to Alaska, Hawaii, and Puerto Rico; and some shipments to unspecified destinations.

Salt shipped to noncontiguous Territories of the United States, 1942–43

Territory	1942		1943	
	Short tons	Value	Short tons	Value
Alaska	4,829	$94,646	3,168	$73,160
American Samoa	14	1,186	1	67
Hawaii	2,668	109,222	1,905	42,854
Puerto Rico	1,004	34,100	1,684	68,723
Virgin Islands	53	3,562	75	5,042

USES

Even before salt is divided into its chemical elements, sodium and chlorine, it has wide utility, and after separation each part has a long list of uses. The accompanying table gives only the broad fields of consumption.

In 1943 increases were noted in five of the seven large uses: Soda ash, chlorine, miscellaneous chemicals, meat packing, and livestock. The quantity used for water treatment was only slightly lower in 1943 than 1942. Table-salt output decreased in 1943. The quantity of table salt required is usually stable and follows the rise in population rather closely. However, in 1942 it increased 188,963 tons and in 1943 decreased 19,259 tons, although the output nevertheless was well above that in normal peacetime years. Part of the decline may be attributed to the fact that large quantities were sold the latter part of 1942, but transportation facilities for moving it to the consumers were not obtained until well into 1943. Requirements of the foregoing seven primary uses absorbed 13 million of the 15 million tons of salt sold or used for all purposes in 1943. However, although many of the other uses require only relatively small quantities, these amounts are important, as no substitute can be used so readily or cheaply as salt.

Salt sold or used by producers in the United States, 1942–43, by classes and uses, in short tons

Use	1942			1943		
	Evaporated	Rock	Brine	Evaporated	Rock	Brine
Chlorine, bleaches, chlorates, etc.	843,970	704,227	654,686	1,138,691	770,620	746,982

	3,517,832	2,802,287	7,373,165	3,993,899	3,259,138	7,961,115

[1] Included under "Other uses."

[2] Includes also exports where use is not specified.

"Other uses" in the table includes several applications that are expanding. More than 66,000 short tons of salt (about 7,000 tons of evaporated and 59,000 tons of rock salt) were reported consumed in the manufacture of synthetic rubber and rubberlike materials. This quantity was exclusive of chlorine and other salt derivatives reported in the table, that were also used therein. A new many-purpose rubberlike plastic called Marvinol, a basic ingredient of which is salt, developed by the Glenn L. Martin Co., Baltimore, Md., was announced in the fall of 1943.

Other miscellaneous uses not given in detail include glass, pulp and paper, fertilizer, tobacco, refractories, clay, brick, tile and sewer pipe, pottery and ceramics, weed killers, and candles.

The war uses of salt, discussed in two previous chapters, were enlarged in 1943. Magnesium-metal manufacture consumed many thousands of tons. The world's largest magnesium plant completed its first full year of operation; the final unit was completed in midsummer of 1943. Other new magnesium-metal making units requiring salt also began operation in 1943. The magnesium plants that dropped out of production in 1943 did not require salt as a basic material.

Common salt is the only raw material from which chlorine is produced. Wartime demand for it increased, and, in 1943, 2,656,293 tons of all classes of salt were consumed in its manufacture. To make 1 short ton of chlorine requires more than 3,000 pounds of salt. As war demands increased, more drastic control of civilian supplies was exerted. Pulp and paper manufacture and rayon and other fabrics suffered further curtailment. Moreover, the War Production Board recommended that ways be developed to utilize waste chlorine gas from magnesium operations and suggested other conservation means.

Within the past year or two a new insecticide, known as D. D. T. (dichloro-diphenyl-trichloroethane) has been developed, in which chlorine is a basic ingredient. This chemical has proved so efficacious in destroying and repelling vermin and other insects that it has been extremely useful to the military forces. There is not enough for civilian use at present.

Salt, when processed with limestone and ammonia, yields soda ash, from which caustic soda and other alkalies are derived. When salt in solution is subjected to the electrolytic method it is broken down into chlorine and caustic soda. The market for these products was large in 1943, augmented by heavy export demand of the sodium compounds, especially by Mexico and South America. Large shipments were made for war requirements and lend-lease.

POST-WAR PROSPECTS

Requirements of some of the present large uses of salt undoubtedly will shrink after the war, but when restrictions on civilian consumer goods are relaxed some compensating gains will materialize. In addition, many of the war-fostered products will shift to other markets, where new adaptations are already indicated.

Salt has attained great importance in magnesium-metal manufacture, and magnesium may find extensive uses in peacetime industry. However, this use of salt may be limited by chlorine-recycling methods now being developed.

Synthetic rubber manufacture, now an established and growing industry which is expected to continue on a substantial basis, promises a large peacetime market for salt. Moreover, new rubberlike materials involving the use of salt derivatives have been invented. Marvinol, now limited to military use in airplane parts, inner tubes for tires, gloves, and similar articles, can be employed for many comparable civilian purposes after the war.

A temporary increase in salt requirements for textile processing and for dyes may be expected when men discard uniforms for civilian clothes and foreign rehabilitation programs reach their peaks. It is also expected that more textiles will be exported, especially cotton.

War demands for chlorine have been so great that civilian supplies have been cut. The dry-cleaning and paper-bleaching industries have been handicapped particularly, and when supplies of chlorine are again available these large uses will be reestablished. The normal needs of the paper industry that are now inadequately supplied are very great. To bleach each ton of dry sulfate pulp to what is known as 80–85 G. E. brightness requires 40 pounds of caustic soda and 140 to 200 pounds of chlorine.

D. D. T. insecticide, mentioned in the discussion of uses, has proved so beneficial in protecting military services against different types of vermin that when it is possible to release it for civilian use it will be much in demand.

Plastics are forging ahead; many of them require salt derivatives. War uses have been found for them that may be adapted to peacetime use. New combinations and uses of rayons have been discovered, adaptable for peacetime applications.

According to the Heyden Chemical Corporation, New York,[7] Latin American drug houses, pharmacies, and laboratories are eagerly awaiting post-war imports of salt derivatives from the United States. However, it should not be overlooked that some of the Latin American countries, notably Brazil and Mexico, are trying to develop their own chemical industries. Mexico is endeavoring to develop its brine wells for chemical manufacture, but the main obstacle has been inability to obtain necessary metals and equipment.

Production of salt for food uses increases steadily with the rise in population. Moreover, whatever part the United States takes in supplying foreign countries with prepared, canned, or processed foods and livestock feed will require its proportionate share of salt. Food specialists have estimated that 40 million tons of food and feed will be necessary for the people and livestock of 20 nations to maintain them until domestic crops are available. Most of the food must come from the Americas—a large part of it from the United States. Studies of post-war food problems now being made by Government agencies include estimates of salt, both for direct consumption and as a constituent or preservative of various food products for both domestic and foreign use. Salt may also be exported in considerable quantities to aid in the rehabilitation of foreign chemical and metallurgical industries.

CHANGES IN THE INDUSTRY

California.—The Defense Plant Corporation unit of the California Rock Salt Co. began operation in 1943 to supply salt for the manufacture of magnesium metal. Mullet Island Salt Co. was not producing in 1943, but resumption of activity is anticipated. Surprise Valley Salt Works was idle in 1943 and has been closed permanently. The Reeder Salt Co. did not produce in 1943 but will resume operation.

---

[7] Oil, Paint and Drug Reporter, November 29, 1943, p. 66.

Colorado.—Although a user of salt, the United States Vanadium Corporation at Uravan (holder of a Government salt lease) did not produce in 1942 or 1943.

Michigan.—Saginaw Salt Products Co. closed its works on June 20, 1943, for the duration of the war. Wyandotte Chemicals Corporation (formerly Michigan Alkali Co.) is a consolidation of the Michigan Alkali Corporation and the J. B. Ford Co., which became effective January 1, 1943.

New Mexico.—International Minerals & Chemical Corporation, formerly Union Potash & Chemical Co., produced common salt as a byproduct. Of the several hundred thousand tons produced annually, only a small quantity is sold to a dealer for livestock use. The salt works at Artesia, formerly operated by Atanacio Pelaez but operated by his son Paz Pelaez in 1943, are now known as Paz Pelaez Salt Lakes. On August 1, 1943, Frank Aubrey acquired the works of the Salt Supply Co. at Carlsbad. Salt is recovered from the dump of the Potash Company of America and is used locally for livestock.

New York.—The Worcester Salt Co., whose evaporated-salt plant at Silver Springs was purchased by the Morton Salt Co. in March 1943, continued to operate as a unit.

Oklahoma.—The plant of the Oklahoma Salt Industries, Inc., reopened late in February 1943 after damage by fire had incapacitated it for output in January and most of February.

Utah.—Jesse Coulson (lake at Nephi) produced no salt in 1943, and the works are closed temporarily. Although Bonneville, Ltd., at Wendover claims that it has unlimited supplies of raw salt it produced none in 1943. The Crystal White Salt Co., which has not produced for the past 3 years, has been reorganized and expects to produce in 1944.

West Virginia.—Pittsburgh Plate Glass Co. began operating the Defense Plant Corporation Natrium plant in July and attained full operation in October 1943.

IMPORTS AND EXPORTS[8]

Salt imported for consumption in the United States, 1942–43, by countries

Country	1942		1943

[8] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the United States Department of Commerce.

Salt imported for consumption in the United States, 1939–43, by classes

Year	In bags, sacks, barrels, or other packages (dutiable) [1]		Bulk			
			Dutiable		Free (used in curing fish)	
	Short tons	Value	Short tons	Value	Short tons	Value
1939	2,121	$14,977	28,451	$58,540	15,461	$27,700
1940	1,024	6,601	16,413	59,029	[2] 12,965	[2] 25,174
1941	1,110	12,156	6,896	17,021	7,426	30,058
1942	367	4,138	953	7,496	[2] 6,434	[2] 17,667
1943	129	2,425	1,129	10,325	-------	-------

[1] Includes 98 pounds valued at $3 imported free in 1942 and 12,939 pounds valued at $493 in 1943.

[2] Includes salt in bags, barrels, or other packages as follows: 1940: 6 tons, $12; 1942: 122 tons, $1,200; 1939, 1941, and 1943: None reported.

Exports shown include salt shipped through lend-lease and supplies for food committees. Most of the exports were rock salt, but enough high-quality table salt and special salt were shipped to raise the value of total shipments.

[1] Less than 1 ton.

WORLD PRODUCTION

In 1943 the Canadian Government began construction of a pilot plant at Malagash, Nova Scotia, to produce from impure salt a product of the required purity and texture for fishery purposes. Since August 1, 1943, all salt associations in Germany have been dissolved except the German Salt Federation. Salt mines in Poland are being utilized by the Germans. Union of South Africa has been forced to depend upon domestic salt sources since the war cut off imports. All orders for salt requirements in New Zealand for the duration of the war will be handled by the Salt Association, composed of importing agents, formed in that country in 1943. Operations to obtain solar salt from sea water in the Lake Grassmere area of New Zealand began in 1943. Free China expected to produce well over a million tons of salt in seven districts in 1943. Occupied China's Changlu fields, Japan claimed, had already exceeded 1942 output by 50 percent by the fall of 1943, chiefly because of opening new fields. Salt output in North China was expected to reach a record.

World production of salt, 1938–43, by countries, in metric tons [1]

SUMMARY

Greatly expanded production of raw materials for the manufacture of magnesium metal and other war uses characterized the magnesite and natural salines industries in 1943. Increased demands for refractory magnesia drew on a variety of raw materials, including magnesite, brucite, dolomite, raw sea water, sea-water bitterns, and well brines. Calcium chloride was used increasingly in road and airfield stabilization. Demand for bromine in antiknock fluids increased, resulting in a record output of ethylene dibromide. Domestic production and imports of Chilean iodine mounted in 1943 in anticipation of a heavy war demand for antiseptics. Labor shortages reduced the production of natural sodium sulfate, but the output of natural sodium carbonates and borates rose. The three salts are used extensively in glassmaking.

Part I.—MAGNESIUM COMPOUNDS

MAGNESITE

Production of magnesium metal in excess of rated capacity of the plant of Basic Magnesium, Inc., Las Vegas, Nev., accounted largely for the tremendous increase in production of magnesite in 1943 over 1942. Refractory demands also were heavy. The American Iron and Steel Institute reported basic open-hearth steel-furnace annual capacity as 83.3 million short tons as of January 1, 1944, compared with 77.6 at the beginning of 1943 and 76.5 on January 1, 1942. The new construction involved during 1943 created such heavy demands for refractory brick that magnesite and sea-water sources combined were inadequate to satisfy the periclase requirements, and much refractory brick was made with a lower periclase content than usual. The program of new construction was so nearly completed by the end of the year that a shift in demand from brickmaking to maintenance grades of magnesite was indicated, and refractory producers were planning their production schedules accordingly.

---

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the United States Department of Commerce.

The authors of this chapter prepared a circular during 1943 dealing with general aspects of the magnesite industry.[2]

Commercial caustic-calcined magnesium oxide is obtained by calcining magnesite or by extracting it from magnesium-bearing liquors or dolomite. Caustic-calcined magnesium oxide is available in many purities and at widely varying prices. That obtained by calcining magnesite is the least pure, a characteristic analysis (calcined basis) being MgO 82.5, SiO_2 11.0, Fe_2O_3 2.0, Al_2O_3 0.5, and CaO 1.8 percent. Such material, however, is quite suitable for oxychloride cements and fertilizers. Somewhat higher grades (83 to 95 percent MgO) are generally used in making magnesium chemicals, including Epsom salts.

Salient statistics of the magnesite industry in the United States, 1939–43

	1939	1940	1941	1942	1943
Crude:					
Mined:[1]					
Short tons	198, 980	333, 166	374, 799	497, 368	754, 832
Value	$1, 465, 190	$2, 487, 969	$2, 655, 547	$3, 874, 334	$6, 071, 596
Sold by producers:					
Short tons	1, 123	2, 133	4, 536	6, 835	4, 090
Value	$15, 752	$32, 810	$54, 045	$57, 350	$47, 788
Average per ton[2]	$14. 03	$15. 38	$11. 91	$8. 39	$11. 68
Imports for consumption:					
Short tons	569	22			
Value	$5, 456	$761			
Caustic-calcined magnesia:					
Sold or used by producers:[3]					
Short tons	10, 157	16, 261	30, 225	[4] 41, 889	191, 792
Value	$310, 102	$512, 607	$1, 052, 077	[4] $2, 028, 126	$11, 497, 505
Average per ton[2]	$30. 53	$31. 52	$34. 81	[4] $48. 42	$59. 95
Imports for consumption:					
Short tons	2, 218	928	864	578	290
Value	$51, 884	$21, 301	$23, 972	$19, 105	$13, 122
Refractory magnesia:					
Sold or used by producers:[5]					
Short tons	86, 077	140, 668	201, 481	273, 661	301, 382
Value	$1, 699, 723	$2, 802, 537	$5, 052, 879	$7, 823, 963	$9, 341, 183
Average per ton[2]	$19. 75	$19. 92	$25. 08	$28. 59	$30. 99
Imports for consumption:					
Short tons	44, 420	30, 951	36, 791	7, 728	9, 233
Value	$800, 664	$551, 536	$824, 068	$280, 342	$310, 407

[1] Partly estimated; most of the crude is processed by the mining companies, and very little enters open market.

[2] Average receipts f. o. b. mine shipping point.

[3] 1939–41: Includes caustic-calcined magnesite and caustic-calcined magnesia from sea-water bitterns; 1942–43: Includes caustic-calcined magnesite and caustic-calcined magnesia from sea-water bitterns, well brines, and raw sea water and from precipitated magnesium carbonate obtained from dolomite.

[4] Revised figures.

[5] 1939–40: Includes dead-burned magnesite and refractory magnesia from sea-water bitterns; 1941: Includes dead-burned magnesite and refractory magnesia from brucite, dolomite, and sea-water bitterns; 1942–43: Includes dead-burned magnesite and refractory magnesia from brucite, dolomite, sea-water bitterns, well brines, and raw sea water.

PRICES

Dead-burned grain magnesite as sold by Northwest Magnesite Co. remained at $22 a short ton f. o. b. Chewelah, Wash., during 1943. This price has been virtually static since 1928. Prices for the mined and synthetic magnesias of the Westvaco Chlorine Products Corporation were unchanged in 1943, except that bulk-mined periclase, 90 percent MgO, was raised from $38.74 a short ton in 1942 to $40.50 in

1943. Following is a price schedule of representative magnesias sold by this firm in 1943 (carlots, f. o. b. California): Caustic-calcined magnesite, bulk—$52.75, powdered—$58.75; calcined (sea-water) magnesia, bulk—$54, powdered—$60; mined periclase, bulk—85 percent, $38.24, 90 percent—$40.50; sea-water periclase, bulk—85 percent, $36.00, 90 percent—$36.50.

The Office of Price Administration published specific dollars-and-cents ceiling prices of basic refractories in M. P. R. 416 of June 28, 1943.

REVIEW BY STATES

California.—Johns-Manville Products Corporation, Redwood City, prepared 85-percent magnesia insulation for steam pipes and boilers, using crude magnesite as raw material. The Marine Magnesium Products Corporation continued to extract high-quality magnesia for medicinal and other purposes from raw sea water at South San Francisco, using the Chesny process.[3] The Permanente Metals Corporation produced magnesia from raw sea water at its Moss Landing plant (built in 1942) for use in its carbothermic magnesium retorts. The Permanente Cement Co., an affiliate of Permanente Metals Corporation, shipped magnesite from Gabbs, Nev., for dead-burning at San Jose, Calif., largely for export to Great Britain. Plant Rubber & Asbestos Works, San Francisco, produced 85-percent margnesia insulation at Emeryville and Redwood City, using sea-water bitterns as the raw material.

Westvaco Chlorine Products Corporation added a fifth kiln at Newark in the spring of 1943 to caustic-calcine crude magnesite. Both calcined dolomite and calcined oyster shells are now used to precipitate magnesia from sea-water bitterns. The magnesia content of the dolomite is precipitated with that of the bitterns. The Westvaco Chlorine Products Corporation mined magnesite at its Western mine at Livermore and its Bald Eagle mine at Gustine, both in California. The ore reserves of the Bald Eagle mine were virtually depleted in 1942, but some high-quality material was produced for blending with Luning (Nev.) magnesite, considerable quantities of which were calcined at the Bald Eagle kiln. Howat reviewed Westvaco's sea-water magnesia process.[4]

Bureau of Mines engineers who examined the Red Mountain magnesite mine in Stanislaus County, which has yielded 140,000 tons of magnesite in the past but is now shut down, estimate indicated reserves at 27,500 to 44,500 tons.[5]

Michigan.—Michigan Chemical Corporation, St. Louis, Mich., completed two new brine wells, one in the Dundee formation, the other in the Sylvania, to provide adequate additional raw material for its second magnesia unit, also completed in 1943. The magnesia is a special caustic-calcined oxide for use in compounding neoprene and other synthetic rubber. The first magnesia unit, completed in 1942, is also producing caustic-calcined magnesia, but partial conversion to periclase is planned for 1944. The magnesias are characterized by very low content of boron, manganese, and phosphorus.

[5] Bureau of Mines, Red Mountain Magnesite Mine, Stanislaus County, Calif.: Bureau of Mines War Minerals Rept. 105, 1943, 13 pp.

Nevada.—The huge magnesium-metal project of Basic Magnesium, Inc., at Las Vegas, which exceeded its rated capacity of 9⅓ million pounds of magnesium a month in the latter part of 1943, required large quantities of magnesite. The mineral was mined, ground, purified by froth flotation, and calcined at Toiyabe, Nev. The calcined product was shipped to Las Vegas for reduction. Operations of this firm have been reviewed by various authors.[6]

The Sierra Magnesite Co., owned jointly by Westvaco Chlorine Products Corporation (Newark, Calif.) and Henry J. Kaiser and his associates (Oakland, Calif.), mined magnesite from the Segerstrom property and other claims near Luning, and the crude mineral was shipped to Newark and San Jose, Calif., for calcining. At Newark the material is caustic-calcined for oxychloride cement and chemical use, whereas at San Jose it is dead-burned for refractory use and caustic-calcined for chemical use.

Texas.—C. E. Heinz continued production of magnesite at Llano, shipping it crude to a firm in Joplin, Mo., for grinding, and to Gardner and Cates, new magnesite producers at Llano, for calcining for fertilizer use. Meramec Minerals, Inc., shut down its Llano mine temporarily and had no output in 1943.

Washington.—The Northwest Magnesite Co., chief producer of refractory magnesite in the United States, mined its Finch and Allen-Moss deposits and operated its seven kilns at Chewelah at near capacity in 1943. Part of the magnesite mined was purified by froth flotation. The unfloated product was used chiefly for maintenance-grade refractories, but the flotation concentrates and some of the regular output went into refractory brick production.

It was reported that the Double Eagle mine 15 miles southwest of Chewelah was being diamond-drilled to determine the extent of its magnesite reserves. This mine produced considerable magnesite during World War I but has been inactive in recent years.[7]

FOREIGN COUNTRIES

Information on foreign developments in magnesite has been meager since the outbreak of the war. The latest Minerals Yearbook table showing world production by countries appeared in the volume reviewing 1939. During the 5-year period 1934–38 U. S. S. R. produced about 534,000 short tons of crude magnesite annually, followed by Austria with 403,000 tons, Manchuria 233,000 tons, United States 157,000 tons, Greece 134,000 tons, and Czechoslovakia 83,000 tons.

Australia.—An excellent review of the Australian magnesite industry appeared in Mineral Trade Notes.[8]

[8] Bureau of Mines, Mineral Trade Notes, Confidential Ser. 13, July 1943, pp. 31–36.

Although magnesite has been produced in Queensland, New South Wales, Victoria, South Australia, and Western Australia, more than 90 percent of the output has come from two deposits at Fifield and Thuddungra in New South Wales. Total production for 1939, 1940, 1941, and 1942 was given as 25,302, 24,877, 27,698, and 34,952 long tons, respectively. During this period about 85 percent was used for domestic refractory purposes, 4 percent was used in magnesium metal, 1 percent was employed for miscellaneous purposes, and 10 percent was exported as calcined material.

Bahamas.—The plant of West India Chemicals, Ltd., to extract magnesia from sea water was not completed in 1943, but officials of the company indicated that construction would be completed in 1944.

Canada.—According to figures released by the Dominion Bureau of Statistics, the value of magnesitic dolomite produced in Canada in 1940 was $897,016 and in 1941, $831,041. In 1942 and 1943 both magnesitic dolomite and brucite were produced. The combined values were $1,059,374 in 1942 and $1,298,775 in 1943. No information on tonnages was published.

Goudge[9] reported expanding uses for the brucite being produced from deposits of brucitic limestone near Wakefield, Quebec:

> The greater part of the brucite magnesia produced at the present time is sold to Canadian Refractories, Ltd., where, after being dead-burned, the granules are used for the manufacture of basic refractories of special grade. The dead-burned granules possess certain physical properties that make them highly desirable for producing fired and chemically bonded basic brick. These brick are currently being used in reverberatory and open-hearth furnaces, in converters, and in electric furnaces in the copper, nickel, steel, and other metallurgical industries. As basic brick, they possess remarkable refractory and spalling resistant properties, particularly in furnaces that are operating at temperatures normally used. An initial trial of brucite brick in the roof of a large reverberatory furnace operating under unusual conditions has given satisfactory results.

Brown[10] discussed a deposit of brucite near Wilkinson, Ontario.

Cuba.—Magnesite was mined by numerous small, independent operators, mostly farmers, near Santa Clara, where it was caustic-calcined for export to Great Britain and the United States.

Manchuria.—One of the world's largest magnesite deposits is in an area of about 60 square kilometers in the Tashichia-Niushinshan Railway sector, according to Mineral Trade Notes, Confidential Series 14, August 1943 (p. 29). The main vein is about 100 kilometers in length, including certain breaks, and is up to several hundred meters in thickness; near Kuanmashan it is 700 meters thick. Reserves are estimated at 580,000,000 metric tons. A typical analysis is MgO 46.36, SiO_2 1.23, Fe_2O_3 0.46, Al_2O_3 0.41, and CaO 0.43 percent.

POST-WAR PROSPECTS FOR THE MAGNESITE INDUSTRY

Severe competition may be expected in post-war years in raw materials for magnesium metal and for basic refractories. Subsidized production, particularly in the magnesium-metal field, has necessarily cut through peacetime considerations of economic freight, cheapest raw material, and cheapest power available in favor of speed. The Truman Committee[11] has indicated that electrolysis of $MgCl_2 \cdot H_2O$ obtained from well brines is thus far the cheapest source of magnesium metal. Unless other reduction processes using magnesite, dolomite, and other raw materials are able to effect tremendous technologic economies so that their costs become comparable to those now used on well brines, they may be expected to close down or operate at a loss after the war.

[10] Brown, I. C., Brucite in Limestone near Wilkinson, Ont.: Econ. Geol., vol. 38, No. 5, August 1943, pp. 408–419.

The basic refractories industry is linked closely with conditions in the steel industry. If the production of basic open-hearth steel declines in the years immediately after World War II as it did after World War I, very little basic brick will be sold because few furnaces will be rebuilt for several years, and the consumption of maintenance-grade material will also be smaller. Post-war basic brick can and probably will be superior to wartime brick, as more high-grade synthetic magnesia will be available per brick. Chesters[12] believes that electrically fused magnesia shapes will be used in increasing quantities in ports and other positions in the furnace where conditions are particularly severe. Both mined and sea-water magnesia might compete in this market, although present practice appears to be limited to mined magnesite.

The necessity of making steel speedily regardless of cost will no longer be a controlling factor after the war. The wartime expedient of ramming proprietary magnesia and chrome mixtures to form the hearth bottom in 10 to 11 days instead of sintering in several layers of grain magnesite in 15½ to 16½ days will be reexamined in the light of ultimate costs.

Domestic producers of magnesite probably will not have to fear an overwhelming influx of foreign magnesite after World War II as they did after World War I, in view of the present tariff protection, which was first afforded the industry in 1922. The present tariff (Tariff Act of 1930) of $9.375 on crude, $18.75 on caustic-calcined, and $11.50 a short ton on dead-burned and periclase should hold imports from Austria, Greece, Manchuria, India, and other countries to pre-war volumes, or about 35 to 40 percent of domestic consumption. Tariff revisions might affect foreign trade profoundly.

Post-war years may bring forth the practicable all-basic furnace, which would reduce the cost of steel materially owing to the melting speed attainable at more elevated temperatures. In present practice the softening point of the silica roofs in basic furnaces limits the temperature to which the furnace may be exposed, and consequently a longer time is required to melt the batch. Research on such magnesia brick for basic roofs in large open hearths presumably will continue after the war and should eventually fructify.

DOLOMITE

Crushed dolomite, both raw and calcined, was used in increasing quantity as a basic open-hearth dressing and for routine furnace maintenance in 1943. Total sales of dead-burned dolomite are given in the following table.

---

[11] Special [Truman] Committee Investigating the National Defense Program. Work cited in footnote 6.

[12] Chesters, J. H., Magnesite Refractories: Iron Age, vol. 151, No. 22, June 3, 1943, p. 50.

Commercial methods of extracting magnesium values from dolomite were reviewed in this chapter of the 1942 Minerals Yearbook.

The United States has been very fortunate in its supply of basic refractories in comparison with some of the other warring countries, notably Germany, which suffers from a shortage of chromite, and Great Britain, which lacks magnesite but has solved the shortage by a wider use of stabilized dolomite brick and grain and of serpentine-magnesia mixtures.[13]

Dead-burned dolomite sold in and imported into the United States, 1939–43

Year	Sales		Imports[1]		Year	Sales		Imports[1]	
	Short tons	Value	Short tons	Value		Short tons	Value	Short tons	Value
1939	671,561	$5,447,554	186	$4,260	1942	1,229,357	$10,817,634	449	$11,260

1941	1,069,887	9,111,172	64	654					

[1] Reported as "dead-burned basic refractory material."

A British trade magazine[14] reports:

> Owing to scarcity of magnesite brick, basic industrial furnaces have turned to dolomite clinker, rammed hard, said to be superior to magnesite brick (which spalled badly), cost little more than half magnesite brick, and did not react with slag to build up as did magnesite and chrome brick.

In Britain refractory dolomite is stabilized by calcining it with serpentine, whereby the lime is converted to stable tricalcium silicate. According to Chesters[15]—

> It is considered safer to operate slightly on the silica rich side of this composition, which means that the brick contains a small amount of beta dicalcium silicate. Since this might otherwise invert, a small proportion of one or more of the known stabilizers is added to the batch.

This procedure differs from American practice, by which the lime is converted to dicalcium silicate with addition of stabilizing iron oxide. The American product softens at a lower temperature than the British on account of its content of the low-melting calcium ferrites, but this is no draw-back for maintenance use. In Britain, however, much stabilized dolomite must be sufficiently refractory for brickmaking; hence formulas are used which require as little stabilizer as possible.

Beta dicalcium silicate, the principal calcium compound in American stabilized dolomite, is unstable and tends to invert to gamma dicalcium silicate with 10-percent volume increase, a phenomenon known as "dusting." To prevent this inversion various stabilizers have been tried, including iron oxide and phosphoric oxide. Zerfoss and Davis[16] suggest that such stabilizers might work in two ways: (1) By isolation of grains of dicalcium silicate, thus interrupting the inversion wave and (2) by stabilizing the crystal lattice by introducing foreign substances.

Seil and Schallis have reviewed in fairly comprehensive fashion methods for separating magnesia from dolomite.[17]

Other aspects of the dolomite industry are reviewed in the Stone chapter of this volume.

OTHER MAGNESIUM COMPOUNDS

The Bureau of Mines traditionally collects production data on "natural" magnesium salts, although in recent years the definition of "natural" has been enlarged to include magnesium hydroxide and magnesium chloride from raw sea water. In preparing magnesium hydroxide the hydroxide anion comes not from sea water but from lime, and in magnesium chloride the chloride anion comes not from raw sea water but from the electrolysis of salt. To obtain complete coverage, the Bureau of Mines now canvasses the magnesium chloride made from magnesite by Basic Magnesium, Inc., and from dolomite by International Minerals & Chemical Corporation, Mathieson Alkali Works, and Diamond Alkali Co., and such data are included with natural magnesium chloride crystallized from well brines. Virtually all magnesium chloride produced was reduced to metal in 1943.

On the other hand, only magnesium sulfate recovered from natural brines is reported, the data not including that made by neutralizing caustic-calcined magnesia with sulfuric acid solution. Magnesium sulfate is used in aqueous solution as a rayon coagulant, in tanning, in pharmaceuticals, as a fertilizer, and for other purposes.

The figures for precipitated magnesium carbonate include material derived from magnesite, dolomite, and well brines and consist mostly of basic carbonate for 85-percent magnesia insulation.

Magnesium compounds (other than magnesium oxide) sold or used by producers (exclusive of those used by producers in making other magnesium compounds) in the United States, 1942–43

Product	1942		1943

Part II.—MISCELLANEOUS SALINES

CALCIUM CHLORIDE

Despite labor shortages for rural road work, sales of natural calcium chloride (and calcium-magnesium chloride) were well-maintained in 1943, reaching 199,796 short tons (75-percent basis) valued at $1,549,565 compared with 224,527 tons valued at $1,733,169 in 1942. There were 11 producers in 1943 and 13 in 1942.

Calcium chloride is derived chiefly from three sources—sea-water bitterns, well brines, and byproduct liquors of the ammonia-soda process. Producers of the last material are not canvassed by the Bureau of Mines, but sales were estimated at 180,000 tons in 1943 compared with 175,000 in 1942. Probably 90 percent of the total calcium chloride available from all sources is thrown away. The amount recovered depends on the market from year to year.

The following firms reported production of calcium chloride (and calcium-magnesium chloride) from natural brines in 1943: California Rock Salt Co., 2436 Hunter Street, Los Angeles 21, Calif., plant at Amboy, Calif.; J. Q. Dickinson & Co., Malden, W. Va.; The Dow Chemical Co., Midland, Mich.; Hill Brothers Chemical Co., 2159 Bay Street, Los Angeles 21, Calif., plant at Amboy, Calif.; Liverpool Salt Co., Hartford, W. Va.; Michigan Chemical Corporation, St. Louis, Mich.; Ohio River Salt Corporation, Mason, W. Va.; Pomeroy Salt Corporation, Pomeroy, Ohio, plant at Minersville, Ohio; Rademaker Chemical Corporation, Eastlake, Mich.; and Westvaco Chlorine Products Corporation, 405 Lexington Avenue, New York 17, N. Y., plants at Chula Vista, Calif., and South Charleston, W. Va.

Calcium chloride and calcium-magnesium chloride from natural brines sold by producers in the United States, 1939–43

[In terms of 75 percent (Ca, Mg) Cl_2]

Year	Short tons	Value	Year	Short tons	Value
1939	108,441	$1,307,717	1942	224,527	$1,733,169
1940	99,536	998,241	1943	199,796	1,549,565
1941	165,932	1,333,370			

Calcium chloride imported for consumption in and exported from the United States, 1939–43

Year	Imports		Exports	
	Short tons	Value	Short tons	Value
1939	996	$12,314	19,382	$318,199
1940	----------	----------	8,907	194,738
1941	7	795	20,777	511,366
1942	1,443	18,926	8,336	223,184
1943	8,000	102,080	12,725	434,933

Road stabilization generally uses about half the total calcium chloride consumed. Surfacing of airfields and roads in military camps at home and overseas has also stimulated demand. For example, the salt was used in stabilizing rolled sand fill on the Adak airfield in the Aleutians campaign.[18]

Most uses of calcium chloride depend either on its hygroscopic properties or the low freezing point of its solutions. Such uses include air conditioning, freeze-proofing of coal and ores, concrete curing, and many others. Chemically, calcium chloride is used to extract lithium chloride from spodumene by heating and to make calcium-soap lubricants. Postponed roadwork and construction are expected to provide a good market for calcium chloride in post-war years.

Prices of calcium chloride, according to the Oil, Paint and Drug Reporter, were the same as in 1942, with the exception noted below: Flake, 77 to 80 percent, carlots, delivered, $18.50 to $35.00 according to zone; solid, 73 to 75 percent, $18.00 to $31.50 ($34.50 in 1942) a ton, carlots, delivered; and 40-percent solutions, $7.50 a ton, tank cars, works.

BROMINE

Producers' sales of bromine compounds established a record in 1943—94,085,937 pounds of contained bromine valued at $19,107,065 compared with 65,880,935 pounds valued at $13,729,383 in 1942. The actual quantity of compounds was 111,205,096 pounds in 1943; comparable figures for earlier years are not available. There were 14 producers in 1943, the same 14 as in 1942. Most bromine enters the market as ethylene dibromide, an antiknock assister. The increasing tempo of the war has multiplied demands for motor fuels, and the growing output of high-octane gasoline has increased rather than diminished the need for antiknock fluids. Nearly all the ethylene dibromide used is made by the Ethyl-Dow Chemical Co. at Wilmington, N. C., and Freeport, Tex., from raw sea water, and the Dow Chemical Co. at Midland, Mich., from well brines. The Ethyl-Dow Chemical Co. began the construction of additional plant capacity at Wilmington, N. C., and Freeport, Tex., to meet the even heavier demands anticipated during 1944. Other bromine compounds, both organic and inorganic, are made by the following firms from sea-water bitterns, dry-lake brines, and well brines: American Potash &

---

[18] Richardson, H. W., Journey to Attu and Back: Eng. News Record, vol. 131, No. 16, October 14, 1943, p. 4.

Chemical Corporation, Trona, Calif.; J. Q. Dickinson & Co., Malden, W. Va.; The Dow Chemical Co., Midland, Mich.; Great Lakes Chemical Corporation, Filer City, Mich.; Liverpool Salt Co., Hartford, W. Va.; Michigan Chemical Corporation, St. Louis, Mich.; Morton Salt Co., Manistee, Mich.; Pomeroy Salt Corporation, Minersville, Ohio; Rademaker Chemical Corporation, Eastlake, Mich.; and Westvaco Chlorine Products Corporation, South Charleston, W. Va., and Chula Vista and Newark, Calif.

Bromine and bromine in compounds sold or used by producers in the United States, 1939–43

Year	Pounds	Value	Year	Pounds	Value
1939	37,882,005	$7,611,400	1942	65,880,935	$13,729,383
1940	59,266,275	11,772,515	1943	94,085,937	19,107,065
1941	68,317,019	11,506,213			

In addition to antiknock fluids, bromine is used in making fumigants, dyes, medicinals, and photographic reagents. Nearly all prices of bromine compounds in 1943 were identical with those in 1942. Ethylene dibromide was quoted over a range of 65 to 70 cents a pound during 1943, f. o. b. plant. Potassium bromide, National Formulary grade, granular, was quoted at 27 to 31 cents a pound; sodium bromide, same grade, was 27 to 30 cents (27 to 31 cents in 1942). Bottled elemental bromine in cases was 25 to 30 cents a pound.

The post-war outlook for bromine production appears good, owing to the direct connection with consumption of automobile and aviation gasolines.

IODINE

Production of iodine increased again in 1943, establishing a new record. There are only two producers—Dow Chemical Co. and Deepwater Chemical Co., Ltd.—and for this reason production data may not be published. In the last year in which three producers operated (1937), output of iodine was 299,286 pounds valued at $242,422. Production has been much higher in recent years, particularly during the war.

Domestic iodine is obtained from oil-well waste waters at Compton, Calif.; the iodine content is estimated at about 45,655 pounds per million gallons of water. Also, considerable iodine is imported from Chile, where it is obtained as a byproduct from caliche. At the end of the year large stocks were being carried by the Chile Nitrate Sales Corporation (about 1,000 tons), and stocks in consumers' warehouses were abnormally large.

The main and best-known use of iodine is as a disinfectant; but its salts have other medicinal and industrial uses, especially in photography, analytical chemistry, and foodstuffs for men and stock.

The price of iodine in 1943 was the same as in 1942, $1.35 a pound less 5 percent, in 150-pound kegs. Resublimed iodine in 5-pound bottles, 50-pound lots, sold at $2 a pound during the year. Virtually all imports were from Chile, as usual.

Crude iodine imported for consumption in the United States, 1939–43

Year	Pounds	Value	Year	Pounds	Value
1939	200,000	$168,238	1942	951,243	$1,051 432
1940	1,244.146	1,296,181	1943	2,744,930	3 041.609
1941	1,010,039	1,121,513			

Considerable current information on iodine and its uses is published in Iodine Facts, available from the Iodine Educational Bureau, Stone House, Bishopsgate, London, E. C. 2.

SODIUM SULFATES AND CARBONATES

Production of natural sodium sulfate in 1943 was handicapped by labor shortages and was 5 percent less than in 1942. On the other hand, production of natural sodium carbonate (all in California), in a vain attempt to meet west coast demands, established a new record, increasing 10 percent in quantity over 1942.

The American Potash & Chemical Corporation completed two expansions in its Soda Products plant at Trona, Calif., for the separation of sodium sulfate and sodium carbonate in the double salt, burkeite. The Arizona Chemical Co., 30 Rockefeller Plaza, New York City, produced sodium sulfate from well brines at O'Donnell and Brownfield, Tex., for the sulfate pulp market but experienced considerable production difficulties owing to the labor shortage. The Cartago Co., 8317 Beverly Boulevard, Los Angeles 36, Calif., shipped trona produced 10 years ago from Owens Lake by the Inyo Chemical Co. but never sold. The Desert Chemical Co., 4031 Goodwin Avenue, Los Angeles, Calif., extracted sodium sulfate from well brines at its Dale Lake plant near Twentynine Palms, Calif. With additional plant capacity completed in 1942, it nearly trebled its sales of sodium sulfate. The Iowa Soda Products Co., Council Bluffs, Iowa (plant at Rawlins, Wyo.), continued its production of Glauber's salt for stock feed.

Natural sodium sulfates and sodium carbonates sold or used by producers in the United States, 1935–43

Year	Sodium sulfates[1]		Sodium carbonates[2]	
	Short tons	Value	Short tons	Value
1935	38,706	$275,943	93,230	$1,173.003
1936	51,608	336,559	102,866	1,106.364
1937	80,053	599.266	104,711	1,191.485
1938	80,210	596,812	100,010	1,235.328
1939	137,479	1,027,876	124,743	1.528,810
1940	187,233	1.528,633	130,034	1.629,283
1941	157,524	1,443,137	146,677	1,822.986
1942	175,033	1,669,983	150,619	2,145,289
1943	165,908	1,553,549	165,993	2,544,086

[1] 1935–38 and 1943: Salt cake and Glauber's salt; 1939–42: Salt cake, Glauber's salt, and burkeite.
[2] 1935–41: Soda ash, bicarbonate, and trona; 1942–43: Soda ash and trona.

The Natural Soda Products Co., 405 Montgomery Street, San Francisco, recovered sodium carbonate at Keeler, Calif., from Owens Lake, Inyo County. The company no longer precipitates sodium bicarbonate as the first raw material; but with the aid of flue gases it carbonates further to the sesquicarbonate, which is precipitated, calcined, pugged, and recalcined to yield a dense soda ash. Owens Lake became a profitable source of natural salts when the city of Los Angeles diverted the flow of Owens River from the lake via an aqueduct in 1915, permitting the lake to evaporate. During the period 1937–39 the city of Los Angeles flooded the lake by returning part of the flow of Owens River, and operations there were seriously curtailed until the lake evaporated once more in 1941. The question of whether the city of Los Angeles has the right to flood the lake is pending before the courts and may determine the future of the two firms operating at Owens Lake.[19]

The Ozark Chemical Co., Mid-Continent Building, Tulsa, Okla., recovered sodium sulfate at its Monahans (Tex.) plant, mostly for sale to sulfate pulp processors. The Pacific Alkali Co., 523 West Sixth Street, Los Angeles (plant at Bartlett, Calif.), extracted soda ash and trona from Owens Lake brines for use in mining and metallurgy, cleansers, and glass. W. E. Pratt, Casper, Wyo., mined sodium sulfate near Casper and converted it to Glauber's salt for stock feed. The West End Chemical Co., 608 Latham Square Building, Oakland, Calif., increased its production of sodium carbonate from Searles Lake.

The principal uses of sodium sulfate are in the manufacture of kraft pulp by the sulfate process, glass, and stock feeds, in dye standardization, and as a flux in metallurgy.

The four producers of natural sodium carbonate in California were unable to supply west coast requirements in 1943, and substantial quantities were shipped in by rail from eastern alkali manufacturers at somewhat higher cost. Sodium carbonate is used chiefly on the west coast in glass manufacture and cleansers. Substantial quantities are used in nonferrous metallurgy and as a precipitant of magnesium carbonate from sea-water bitterns. The post-war outlook for the industry appears good if water-transport rates to the west coast via the Panama Canal do not become so low as to permit competition with eastern producers.

Production data for sodium carbonate produced by the ammonia-soda process for the last 3 years, according to the Bureau of the Census, are: 1941, 3,606,826 short tons; 1942, 3,788,583; and 1943, 4,407,618. There are no official consumption figures for sodium carbonate, but the following table, published in Chemical and Metallurgical Engineering, may be indicative.

---

[19] Pacific Reports 2d, vol. 132, January 1943, p. 553.

Estimated consumption of sodium carbonate in the United States, 1940–43, by industries, in short tons[1]

Industry	1940	1941	1942	1943
Glass	860,000	990,000	1,100,000	1,200,000
Soap	200,000	170,000	165,000	150,000
Caustic and bicarbonate	780,000	1,033,000	960,000	1,010,000
Other chemicals	730,000	800,000	840,000	950,000
Cleansers and modified sodas	65,000	70,000	80,000	85,000
Pulp and paper	123,000	155,000	145,000	155,000
Water softeners	55,000	70,000	80,000	95,000
Petroleum refining	20,000	23,000	18,000	20,000
Textiles	45,000	60,000	56,000	58,000
Nonferrous metallurgy	248,000	150,000	260,000	450,000
Miscellaneous		225,000	230,000	370,000
	3,126,000	3,746,000	3,934,000	4,543,000

[1] 1940: Chem. and Met. Eng., vol. 50, No. 2, February 1943, p. 105; 1941–43: Chem. and Met. Eng., vol. 51, No. 2, February 1944, p. 113.

Domestic salt cake was quoted at $15 a short ton, bulk, works; anhydrous sodium sulfate at $1.70 to $1.90 per hundredweight, works; and Glauber's salt at $1.05 to $1.25 per hundredweight in 1943, according to the Oil, Paint and Drug Reporter. Soda ash, calcined sodium carbonate, was sold at $0.90 to $3.25 a hundredweight, depending on grade and other factors.

Sodium metal.—There are only two domestic producers of sodium metal—E. I. du Pont de Nemours & Co., Inc., Wilmington, Del., and Ethyl Gasoline Corporation, 405 Lexington Avenue, New York City—and therefore production data may not be published. Sodium metal is made by electrolysis of fused salt, NaCl. About half the output is used in making tetraethyl lead (the gasoline antiknock), and most of the other half is used in the synthesis of dyes and other organic chemicals. Some is used as a metal in alloys, as a scavenger, and in the liquid phase as a heat-transfer medium. Sodium is available in tank cars or in 2½- or 12-pound bricks packed in drums. Metallic sodium was placed under allocation November 15, 1943, to assure adequate supplies for the manufacture of tetraethyl lead.

BORATES

Production of boron minerals in 1943 recovered from the 1942 slump and has been exceeded only by the output of 1941. Five producers, all in California, reported shipments—the same five firms that produced in 1942.

American Potash & Chemical Corporation, 122 East Forty-second Street, New York City, extracted borax from the brines of Searles Lake at its Trona (Calif.) plant and sold borax, dehydrated borax, and boric acid for domestic and foreign consumption in a wide variety of uses, but principally in glass. The brine is pumped from wells approximately 70 feet below the crust of the lake and transmitted via pipe line to the plant 4 miles away. Pacific Alkali Co., 1223 Pacific Mutual Building, Los Angeles, recovered borax from the brines of Owens Lake at Bartlett, Calif., chiefly for export.

Pacific Coast Borax Co., the oldest and one of the largest producers, operated its kernite mines at Boron, Calif., and its Wilmington (Calif.) refinery (making over 200 boron derivatives, including kernite concentrates, borax, and boric acid) for domestic and export trade.

Connell[20] reviewed the mining and processing of kernite by the Pacific Coast Borax Co. Kernite is mined by the shrinkage-stoping and room-and-pillar methods from the Baker deposit at Boron near Mojave; shipped to a refinery at Wilmington, Calif., on the coast; dissolved in water with the aid of heat and pressure; and reprecipitated as sodium tetraborate, or borax.

United States Borax Co., 510 West Sixth Street, Los Angeles, mined colemanite (crude calcium borate) near Shoshone, Inyo County, Calif., for conversion into borax at a nearby refinery.

West End Chemical Co., 608 Latham Square Building, Oakland, Calif., recovered borax from Searles Lake at its Westend (Calif.) plant and sold both borax and dehydrated borax.

Salient statistics of the boron-mineral industry in the United States, 1939–43

	1939	1940	1941	1942	1943
Sold or used by producers: [1]					
Short tons:					
Gross weight	245, 284	243, 355	301, 282	226, 723	256, 633
B_2O_3 content	81, 800	80, 900	95, 200	77, 600	87, 600
Value	$5, 689, 797	$5, 643, 390	$6, 785, 662	$5, 733, 648	$6, 401, 507
Imports for consumption (refined): [2]					
Pounds	[2] 774	752	2, 025	------------	------------
Value	[2] $170	$185	$92	------------	------------
Exports:					
Short tons	91, 139	64, 313	41, 793	36, 542	26, 877
Value	$3, 230, 304	$2, 456, 523	$1, 893, 500	$1, 562, 794	$1, 282, 372
Apparent consumption: [3]					
Short tons	154, 145	179, 042	259, 490	190, 181	229, 756

[1] 1939: Borax, colemanite, kernite, ulexite, and boric acid; 1940–41: Borax, kernite, boric acid, and colemanite; 1942–43: Borax, anhydrous sodium tetraborate, kernite, boric acid, and colemanite.

[2] Also 348 pounds of crude valued at $7 in 1939; 525 pounds of crude valued at $7 in 1943.

[3] Quantity sold or used by producers plus imports minus exports.

The price of technical borax, granular, bulk, freight allowed, remained at $41.50 a short ton throughout 1943, the same as in 1942, according to E&MJ Metal and Mineral Markets.

Owing to the fact that producers report the quantities and values of their boron products at various stages in the process of refining (ranging from crude ore to finished salts and boric acid) it has been decided to add an entry in the boron minerals salient statistics table indicating the B_2O_3 content of all ores and salts produced.

Container glass is today using most of the output of boron minerals, according to producers' estimates. Borax in the glass batch enables glass to withstand, with minimum breakage, treatments such as washing and pasteurizing; and borax improves the tensile strength, elasticity, and hardness of glass, thus facilitating handling and shipping. In normal times the chief use of borax is in porcelain enamels, but this market must remain quiescent until steel is again generally available for stoves, refrigerators, kitchen utensils, and similar articles.

Boron compounds are used in water treatment, soap formulas, pharmaceuticals, alloy steels, flame-resisting paints, fertilizers, and various other commodities.

---

[20] Connell, George A., Technology of Borax Production as Practiced by the Pacific Coast Borax Co.: Paper delivered at Am. Chem. Soc., One Hundred Sixth Meeting, Pittsburgh, Pa., September 6–10, 1943, and available from the Pacific Coast Borax Co., 51 Madison Ave., New York, N. Y.

Two new improved optical glasses made without sand and using boric acid have been announced. In addition to boric acid, the first of these glasses employs zinc oxide, alumina, and beryllia; and the second, oxides of tantalum, tungsten, and lanthanum.[21]

The New Jersey Zinc Co., 160 Front Street, New York, announced a zinc borate paint for flameproofing fabrics, tents, lifeboat coverings, and hatches.

The American Potash Institute, Inc., 1155 Sixteenth Street NW., Washington, D. C., issues frequent bibliographies on the use of boron fertilizers, as a series known as "List of References to Boron Literature." Published in 1943 were B–25, January–March; B–26, April–June; and B–27, July–September.

With the exception of small quantities of boron minerals produced in Italy, Turkey, Tibet, and certain South American countries, the United States has been virtually the world's supplier in recent years, and a considerable proportion of American production is exported in normal times. Reopening of foreign markets after the war should go far in absorbing material diverted to war uses at present.

JEWELRY INDUSTRY IN 1943

Retail jewelers have never had a year like 1943. Sales of taxable jewelry totaled $998,094,416, or 26 percent above those in 1942 ($792,000,000). Gains over 1942 reached their peak in the second quarter of the year, then tapered off. The causes were an all-time high national income ($142,000,000,000, compared with $115,500,000,000 in 1942); a large number of weddings (1,725,000—only exceeded by the 1,800,000 in 1942); reduced competition from other luxuries and semiluxuries; and much money in the hands of free-spending warworkers. The increased sales were without Government stimulation. All men of draft age in the industry were nondeferable under the Selective Service System, and the 10-percent excise tax on jewelry sales was effective throughout the year.

Christmas sales were 20 percent larger than in the previous year and began as early as late September, so that our boys (and girls) overseas would get their gifts by Christmas. Gold jewelry, diamonds, costume jewelry, and Swiss watches were in particular demand.

Sales were largely of medium-price articles, although both retailers and art galleries disposed of a number of items running into five figures.

Manufacturing jewelers, with their supplies of metal markedly restricted by Government regulations, continued to make what jewelry they could, although the industry was converted, where possible, to war work. Their sales early in the year were large, although less than those of retailers. By August, however, sales slipped below those of 1942, and stocks decreased. Wholesalers began to sell from stocks accumulated in a happier day.

Luckily, now that the Office of Price Administration has removed price control from all diamonds, the black market in these gems has evaporated. The recently increased excise tax on all jewelry (from

10 to 20 percent, effective April 1, 1944) will scarcely increase the tax collected, as it is likely to cut down on gross sales and may create a black market, for certain of the smaller refugee "merchants" will sell without charging the tax. L-45 (Karat-Gold Limitation Order) has created a black market in carat-gold goods, particularly in wedding rings. It centers in New York. Some of the skilled workmen of the industry have left their former employers and work for fly-by-night shops or work overtime in them. Such shops have no difficulty in getting, at a price, the gold and the modicum of copper required. Low-carat gold rings and some electroplated silver rings are being sold surreptitiously as 14-carat rings.

On January 15, 1944, the War Production Board announced that approximately 50 percent more gold and palladium could be used by jewelers in 1944 than in the latter half of 1943. This liberalization of L-45 will retard the growth of the black market but is not sufficient to crush it.

A year or two hence—unless in the meantime peace is declared—the position of most retailers is not likely to be enviable. In 1943 most jewelers sold their accumulated stock, and adequate replacement is difficult or impossible; further, competent help is hard to find. Perhaps the less-aggressive sales attitude which the British retailers have adopted—namely, sell only that which can be replaced—is to be preferred. Present profits subject to current high tax rates are less desirable than having a going concern when the war ends. More retailers should specialize in diamonds, and they should replenish their stocks from heirloom jewelry. Some few retailers have shut up shop; others are shortening store hours appreciably.

POST-WAR PROSPECTS

As to the post-war outlook, competition within the retail trade will be keen, but reconversion of the jewelry trade should require less time than that of most other industries, and jewelers should be in an advantageous position compared with most of their competitors in being able early to extract from ex-warworkers some of their accumulated savings. Within the industry there will presumably be more competition from department stores, upstairs distributors, and door-to-door solicitors, because medium-price articles are likely to make up a larger percentage of the gross than formerly.

FASHIONS IN JEWELS

Jewelry was never more popular than in 1943 among American women who realize that beautiful jewelry, appropriately worn, may increase the charm of a smart gown. The vogue for gold, often in two or three tints, continued to grow, and more silver was used than ever. Diamonds still show to best advantage when set in white metal. Palladium, the substitute now used for platinum, is so light that it is ideal for earrings, and palladium pins do not "pull down" flimsy textiles. Floral designs and patriotic motifs were particularly popular, followed by geometric, leaf, and Latin-American and Chinese designs. Bizarre insects, animals, and dwarfs were common, particularly in cheaper jewelry. Multiple-use clips and other double-duty jewelry and ensembles, all mounted with the same gem, were widely used. Earrings and clips were much worn, bracelets and necklaces to a less extent.

Owing to a shortage of small cut, fewer melee were used in mountings. Huge topaz and aquamarine were mounted in bracelets and bridge rings. Diamond, ruby, and sapphire (the vogue for varied-colored sapphires is expanding) led in popularity, followed by natural and cultured pearl, emerald, topaz and topaz quartz, aquamarine, and moonstone. The insistent demand for diamonds, together with the patriotic motif in jewelry, caused colorless, then red and blue stones to be dominant, followed by green and yellow, and then purple and black stones.

American knowledge of precious stones continues to expand, and American women today use effectively three or four times as many varieties as did their mothers. High school and college girls love their jewelry, and turquoise and pearl are particularly popular with them.

DOMESTIC PRODUCTION

The production of gem stones throughout the world was blighted in 1943 by war, but nowhere more than on the North American Continent, which has no gem field of prime importance. In 1942 a rough estimate of the value of uncut stones used in jewelry and related industries was $150,000; in 1943, it was not over $67,000. The decrease was due to three principal factors: Professional gem miners turned to the mining of one or more of the strategic minerals; amateur collectors did not have enough gasoline (or tires) to rush out over the week-end to well-known mineral deposits; and the best customers of the trade, touring automobilists, were, for the same reason, a tradition. The increased mining of pegmatite bodies for mica and other strategic minerals apparently did not increase the production of beryl and other gems of pegmatite origin; perhaps the miners high-graded these. As opposed to gem miners, professional and semiprofessional lapidaries in the Northwest were busy furnishing jewelers with cabochon quartzes and agates, cut from stones collected in previous years, to supplant the European cheap jewelry which was no longer available. In the East, several firms are dyeing onyx black to be used in cheap jewelry.

As producers, the leading States ranked as follows: Montana, California, Wyoming, Oregon, Washington, Colorado, and Idaho.

The Montana sapphire industry produced about 20,000 ounces of sapphire worth some $20,000. The Perry-Schroeder Mining Co. of Helena was the principal producer. Charles H. Carpp of Philipsburg was also a producer. Although a small part of the product was of gem grade, practically all of it was sold for cutting into watch and instrument jewels. Toward the end of the year, synthetic corundum undercut the natural market badly.

The agate and other quartz species in 1943 were of the same order of value produced as sapphire. Dr. H. C. Dake reports that production, even at well-known localities in Washington and Oregon, was greatly reduced from that of previous years. Idaho's production decreased also.

The moss agate in the gravels of Yellowstone River in Montana continues to be collected, but to a smaller extent than in previous years. The collectors bring these to the two principal cutting and curio shops in Billings. After splitting the pebbles, the shops buy what small percentage they fancy.

Perhaps $15,000 worth of Wyoming jade was sold in 1943. Nephrite occurs mainly as boulders and pebbles, some of them large, on the hill slopes near Lander. It also occurs in place. The better material, green translucent nephrite, brings as much as $5 a pound, although the 4,000 pounds sold to lapidaries brought but $3 a pound. Several large boulders, one weighing over 8,000 pounds, were found in 1943. A boulder weighing 2,410 pounds and polished on one side is now on exhibition at the Chicago Natural History Museum. Some of the material is being stocked, in the hope of selling it to China after the war to be cut into objets d'art. All the Lander material is nephrite.

Turquoise production languished. The King and Ashcroft mines in Colorado produced turquoise in 1943, although the Hall mine (principal producer in 1942) did not operate. It is stated that the Mineral Park (Ariz.) district produced some turquoise, as did certain deposits in western New Mexico. The manufacturers of Indian jewelry, however, look to Nevada and Colorado for their turquoise, although there is no evidence at hand that the Nevada mines operated in 1943. A turquoise deposit in Culberson County, Tex., is being developed.

Alfred M. Buranek reports that some good plume agate was collected at Jericho, Juab County, Utah, as was fortification agate at the new locality in Sanpete County near Levan; that some 500 pounds of fine variscite was mined at Lucin; that some superb malachite and azurite were recovered from the Dixie Apex mine near St. George; that the black obsidian with white christobalites found near Black Creek (trade names, Flowering Obsidian, Night Blooming Cereus, and Snowflake Obsidian) is increasing in popularity; and that Utah Jade, fabricated into book ends, table tops, and other articles, is merely a quartzite of the Harrison formation of pre-Cambrian age colored by chrome-bearing mica.

Stuart A. Northrop states that some attractive "moonstone" (presumably sanidine) appears to be coming from Grant County, N. Mex., and that during the year there was a small demand for garnets from the Navajo Reservation, staurolites from Taos County, and agate from near Hot Springs, Sierra County.

Stanley I. Perham reports among other gem stones found in Maine during the year: Purple apatite at Greenwood, Oxford County; beryl approaching a light emerald in color and golden beryl from West Peru; fine golden beryl from Waterford and Brunswick; white caesium beryl and rose quartz at Newry; and aquamarine and asteriated rose quartz from Albany.

Little pipestone (only about 1,000 pounds) was mined at Pipestone, Minn., as most of the former diggers are in the army.

Scott's Rose Quartz Co. (South Dakota) reports the sale of about 800 pounds of rose quartz, although little was mined because of the labor shortage.

Edward P. Henderson reports that the National Museum has an 18.7-carat brilliant cut from transparent scheelite from Kernville, Kern County, Calif. The stone has good brilliancy although a bit frosty, and makes quite an attractive gem.

Quartz for use in radios and radar equipment was mined in California, Arkansas, and North Carolina. The usability of American quartz is low, but some of it may be suitable for objets d'art.

A few small diamonds were recovered at Murfreesboro, Ark. (see Diamond—World production).

Other gems produced in the United States in 1943 included agate (Maine); aquamarine (Maine, North Carolina, and Virginia); bloodstone (San Bernardino County, Calif.); chrysocolla (Arizona); golden beryl (Virginia); jasper (Maine); banded "onyx" (calcite) (Lusk, Wyo.); malachite (Arizona); petrified wood (Arizona); pink beryl and tourmaline (Pala district, Calif.); and smoky quartz (Maine).

CANADIAN GEM STONES

A small amount of clear, glassy beryl from the Winnipeg River and Bird River pegmatite areas in Manitoba is cut for the Winnipeg tourist jewelry trade. Dr. A. L. Parsons reports that excellent rock crystal has been found in Lansdowne Township, Ontario, and a little iolite in Haliburton Township. Both localities furnish material for amateur lapidaries.

IMPORTS [1]

The value of imports of precious and semiprecious (real and imitation) stones (exclusive of industrial diamonds) totaled $72,109,788, over two and one-half times that of 1942. The big increase was in the importation of rough and cut diamonds and cut precious stones. Details are as follows:

Precious and semiprecious stones (exclusive of industrial diamonds) imported for consumption in the United States, 1942–43

Commodity	1942		1943	
	Carats	Value	Carats	Value
Diamonds:				
Rough or uncut (suitable for cutting into gem stones), duty free	278,437	$11,546,712	751,674	$37,443,240
Cut but unset, suitable for jewelry, dutiable	126,004	14,640,236	193,701	31,453,840
Emeralds:				
Rough or uncut, free	6,506	676	8	248
Cut but not set, dutiable	21,209	205,717	3,194	32,508
Pearls and parts, not strung or set, dutiable:				
Natural	----------	179,169	----------	167,284
Cultured or cultivated	----------	----------	----------	107
Other precious and semiprecious stones:				
Rough or uncut, free	----------	72,895	----------	47,726
Cut but not set, dutiable	----------	1,583,600	----------	2,589,904
Imitation, except opaque, dutiable:				
Not cut or faceted	----------	195	----------	2,621
Cut or faceted:

Imitation	----------	1,544	----------	----------
	----------	28,520,070	----------	72,109,788

---

[1] Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the United States Department of Commerce.

GOVERNMENT REGULATIONS

Owing to the war, Government regulations covering the jewelry industry and originating in 1943 were legion. Many were primarily to raise revenue and to discourage luxury spending (for example, the 100-percent tax on jewelry sales in Great Britain); others to conserve labor or to control the supplies of valuable metals; others to prevent the export of easily converted wealth; and still others to protect home industries (for example, to protect its precious stone industry, Brazil requires a permit, difficult to obtain, to import synthetic stones).

In Germany all shops selling jewelry were closed in February, and jewelry manufacture was prohibited after April 1. In all, 3,300 shops were closed, the blow of course falling most heavily on middle class proprietors. German war prisoners in Canada, remembering what happened to the mark after World War I, are buying plain gold rings.

The Nazis closed jewelry shops in the Netherlands in March. The Germans continue to buy any fine jewels they can in the Netherlands black market, even if the prices are exorbitant. On September 29, the Nazi-controlled Department of Commerce decreed that pearls, rubies, sapphires, and emeralds could be bought only against surrender of ration coupons. Precious stones were one of the few means left for the Netherlanders to invest money. The decree will force such excess money into the Netherlands Bank, where the Nazis can confiscate it.

EFFECT OF WAR ON GEM-STONE TRADE

War continues to change the picture of the gem trade; for example, the recent reopening of the Dutoitspan pipe is a direct result of the tremendous fall in world diamond stocks due to war's insatiable demand for industrial diamonds and the large demand for gem diamonds. We are, on the other hand, cut off from the ruby and sapphire fields of Burma and Thailand; the Burmese jade fields are languishing because China, their main market, is no longer open to them; and the Badakshan lapis lazuli mines have lost their former market, Germany.

Our boys overseas are matching their wits with those of local jewelers of many lands. Ceylon's precious stones have mounted in price, and not only are jewel brokers bidding for them, but our boys are getting their part there as well as in India. Our soldiers have already purchased most of the lovely old silver jewelry in the Algerian shops; Italians are now attempting to foist flimsy trinkets on them as fine heirlooms.

Our domestic production of gem stones is down, since professional mines are mining strategic minerals, and amateurs have neither the tires nor the gas to seek them. Similarly, in Brazil accelerated quartz and mica mining draws from the same pool of labor as diamond and other gem-stone mining, and in consequence the production of the latter two is affected adversely.

In Great Britain, wedding rings are so scarce that some brides use their grandmothers' or mothers' rings. The production quota of 9-carat utility rings has been increased, and many brides are reluctantly accepting them rather than the better rings they hoped to wear. South African brides refuse to accept them.

War has brought about important (though possibly temporary) geographic adjustments in various branches of the jewelry industry. The wide dispersal of the cutting of gem diamonds is an instance in point. Argentina is making the cheap jewelry which it once imported and even exports some of it. Great Britain and the United States now produce synthetic sapphire and ruby, and after the war these will be used for jewelry. Czechoslovak refugees in each country are making fine colored glasses to be used as imitation precious stones.

One of the few humorous incidents of the war is the fact that our boys find that the South Pacific island natives will do nothing for money but are enchanted to work hard for second-hand "junk" jewelry. Tons are being collected and sent to the Pacific isles.

DIAMOND

Paradoxical as it seems, in 1943—the fifth year of World War II—the diamond industry reached an all-time peak of prosperity, owing to an unprecedented demand for industrial stones and an enormous demand for gem diamonds created by high war wages and fear of inflation.

Production continued downward, that of 1943 being but 88 percent of the 1942 output and only 63 percent of the production in 1940. The war demand has dangerously reduced the large stocks of both industrials and gem stones accumulated in the past 16 years; in consequence, the United Nations have requested the Belgian Congo to double its production of crushing bort, and DeBeers has reopened Dutoitspan, one of its pipe mines. Diamond cutting continued to increase.

Price of gem stones, both rough and cut, surged forward; that of industrial stones continued stable, although sellers of industrial stones claim that the quality of the shipments had deteriorated, amounting to a price rise.

The division between diamonds used for industrial purposes and those used ornamentally is yearly becoming more sharply defined.

Share dealings.—The shares of diamond-mining companies, virtually all of which are listed on the London Stock Exchange, were market leaders and doubled in value in 1943, accentuating their rise in the past 2 years. Indeed, one who had put $1,000 in these shares in mid-1941 would have a value on paper of $4,500 by mid-1943. The 1943 advance culminated late in June; thereafter the market weakened a bit. The companies paid generous dividends in 1943.

Market.—In 1943 the Diamond Trading Co., which in normal times sells about 95 percent of the world output, is said to have sold almost £20,000,000 worth of rough (£10,694,671 in 1942), the highest sales since 1919. Sales of both cuttables and industrials gained. The company instituted the practice of selling crushing bort by the kilogram, although American brokers continue to use the carat.

In 1943 the United States bought large quantities of medium-size diamonds, and the United States, Palestine, and South Africa bought cuttables for their cutting shops. Black markets thrived in all the warring nations, diamonds being a favorite investment of citizens of conquered countries and those of belligerent countries whose war future is precarious. Americans bought fine diamonds heavily, partly to supply their craving for beauty, partly as a hedge against inflation.

Since 1939 the price of fine large rough has increased at least 70 percent, and the price is boosted by the Trading Co. on every favorable occasion. As to cut stones, melee under ¼ carat has tripled or quadrupled in value since 1939; ½-carat sizes have gained 80 to 125 percent; 1-carat stones, 67 to 100 percent; and larger stones progressively less. Increases include the excise tax (1943, 10 percent; 1944, 20 percent). Diamonds have never sold higher; and prices may have been advanced too rapidly for the good of the industry.

Stocks of both fine rough for gem purposes and many grades of industrials have been reduced, possibly to a dangerous degree, since demand has markedly exceeded supply. In America the cutters have a more or less satisfactory supply of most grades of rough; but supplies of melee and fine cut in certain sizes are short.

Imports.—As the following table shows, in 1943 the total value of imports of gem diamonds was 163 percent higher than in 1942, the gain being particularly great in rough or uncut diamonds (225 percent); that in cut was also large (115 percent). The quality of both rough and cut paralleled that of 1942, the rise in price during 1943 accounting for the increased prices per carat.

Cutting.—Before 1940 the Low Countries cut about 90 percent of the world's diamonds. Since then the industry has been widely scattered over the world. Some 10,000 artisans and apprentices (about one-third of the pre-war force) now supply (except in time of lock-out or strike) an adequate quantity of cut stones. Palestine (3,000 employees), the United States (1,800 employees), and South Africa (550 employees) are now the principal centers of cutting. Brazil, Great Britain, Cuba, Puerto Rico, Canada, India, and Borneo are less important centers.

With the rebirth of the Belgian and Netherlands industries after the war, competition will be keen. Perhaps the United States and South Africa can continue—notwithstanding fantastically high wage scales—to cut large stones profitably, and Palestine may be able to cut small stones.

World production.—Owing to the war accurate diamond-production statistics are not available, but the estimates in the following table are believed to be fairly reliable. World production (gems and industrials) in 1943 is estimated to have been 8,191,360 carats (1.64 metric tons), valued at $27,000,000. The quantity was about 12 percent less and the value 4 percent less than in 1942. The quality was slightly better than in 1942, cuttables making up, by weight, some 22 percent of the total. Belgian Congo was the leading producer, both as to weight and value, although the collective value of the British production exceeded that of the Belgian colony. As DeBeers reopened Dutoitspan on September 1 pipe mines yielded almost 1 percent of the production, but over 99 percent came from placer mines.

The following table shows, as accurately as available statistics permit, world production for the past 5 years.

World production of diamonds, 1939–43, by countries, in metric carats

[Including industrial diamonds]

Country	1939	1940	1941	1942	1943
Africa:					
Angola	690,353	784,270	787,000	[1] 791,850	800,000

British Guiana	32,491	[1] 26,764	27,000	27,000	27,000
Other countries [4]	19,000	31,750	34,350	40,836	29,650
Grand total	12,500,553	13,012,525	9,104,978	9,258,734	8,191,360

Estimated.

1939–40: Exports; 1941–43: Production.

[3] Cape and Transvaal, without Namaqualand, estimated at 53,210 carats.

[4] 1939: Venezuela, India, Borneo, New South Wales, and U. S. S. R.; 1940–41: Borneo, India, New South Wales, U. S. S. R., and Venezuela (Venezuela produced, respectively, 14,525 and 29,399 carats); 1942: Borneo, India, New South Wales, Rhodesia, U. S. S. R., and Venezuela (Venezuela produced 31,570 carats); 1943: Venezuela (23,020 carats), Borneo, India, New South Wales, U. S. S. R., United States (Arkansas), and Bolivia.

Because of a shortage of supplies, the Belgian Congo produced 19 percent less diamond in 1943 than in 1942, and Brazilian and the South African alluvial production decreased; that of South-West Africa increased somewhat.

Dr. N. R. Junner published a most valuable bulletin on the Gold Coast diamond fields. Sierra Leone produced two large gem stones during the year, thus joining the select coterie of large stone producers—India, Borneo, South Africa, and the Bagagem district in Brazil. The occurrence of diamonds in eastern Bolivia is reported.

The Federal Bureau of Mines did some exploratory work on the diamond-bearing kimberlite pipe at Murfreesboro, Ark. It put down 51 bucket drill holes 30 inches in diameter through the softer surface material. They ranged from 10 to over 50 feet in depth, averaging slightly over 30 feet. In all, over 425 tons of samples were taken. These have been washed by South African methods and all diamonds recovered with adequate safeguard to insure reliability of results. The stones recovered are being evaluated by a number of experts and the data assembled and studied. Results are not yet available.

Industrial diamonds.—In 1835 the great British scientist, Sir David Brewster stated that were the diamond not as a gem the "head of the mineral kingdom," "it would have attained the same distinction from its great utility in the arts." World War II has certainly proved the truth of the statement. There is no important war weapon used by our forces that does not employ the diamond in its manufacture.

The use of industrial diamonds, particularly of crushing bort, continues to increase by leaps and bounds under the stimulus of war, although much of the gain will be retained in post-war times. Consumption greatly exceeds production. Finer grades continue scarce, but research and experience prove that the grades available are satisfactory substitutes.

Germany and Japan are already pinched for industrial diamonds, hence their desperate efforts to smuggle this superabrasive into the homelands. Stocks in the United States are adequate, and in case of need the large stock established in Canada by the Diamond Corporation and the principal producers is available.

Before the war the United States consumed about 1,250,000 carats of industrial diamonds a year. The figure had increased to some 10,000,000 carats in 1943. World consumption must be double present production.

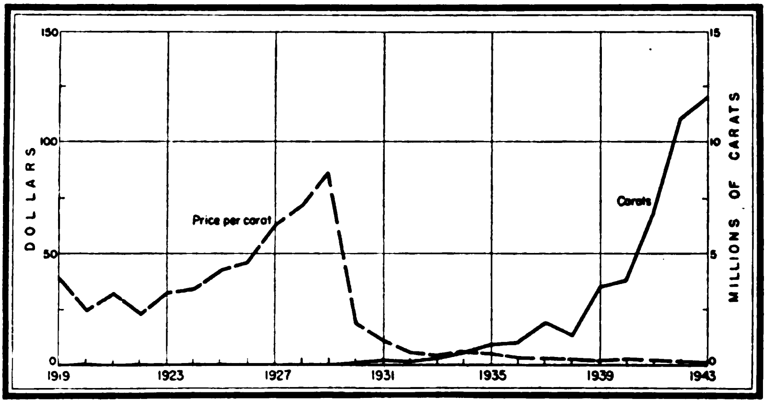

FIGURE 1.—United States imports and average price per carat of industrial diamonds, 1919–43.

Figure 1, prepared by Herbert Backman, illustrates the two outstanding features of the industrial diamond trade in the past quarter century: The tremendous increase in use, particularly since 1938, and the sharp decrease in the average price of the stones used. In 1929 the carbonado market—then the principal source of our imports—was cornered. Now most of our consumption is that of crushing bort.

Imports of industrial diamonds into the United States during the past 5 years were as follows:

Industrial diamonds (glaziers', engravers', and miners') imported for consumption in the United States, 1939–43

Year	Carats	Value		Year	Carats	Value	
		Total	Average			Total	Average
1939	3,568,730	$9,725,683	$2.73	1942	11,203,704	$22,057,577	$1.97
1940	3,809,071	11,026,563	2.89	1943	12,172,679	21,938,368	1.80
1941	6,882,248	14,908,809	2.17				

RUBY, SAPPHIRE, AND EMERALD

The production of fine gem stones—rubies, emeralds, and sapphires—is meager and entirely in the hands of individuals and small partnerships. The ruby mines of Burma and the sapphire mines of Thailand and Indochina may still be operated on a small scale by the natives, but they are shut off from their principal markets, America and western Europe. The Japanese market must be quite restricted.

The Muzo emerald mines have not been operated for several years. The Ceylon sapphire mines and perhaps those of Kashmir are presumably booming, and the American troops stationed in the East constitute an enlarged local market. Before the war the Australian sapphire mines were languishing, and war has also interfered with production at most of the minor gem localities, including the Russian emerald mines and the Montana sapphire mines. Egypt, in its program to develop the mineral resources bordering the Red Sea, has recently announced that the ancient emerald mines are to be reopened; but little, if any, desirable material can be expected from this source.

Paradoxically, there is no dearth of fine gem stones, which, incidentally, have never been more popular. The supply, however, is coming from stocks and from old jewelry, now being bought by almost every jeweler. The restricted production and the phenomenal demand, which are likely to continue after the war, point to higher prices in the future.

Since the war, New York and London have supplanted Paris as the principal colored-stone markets and are now receiving stones direct from the East.

LESSER GEMS

Brazil continues to supply our market with fine and barbarically large aquamarine, topaz and citrine, and other precious stones.

The press reports the Government of Kashmir has authorized exploitation of an opal deposit. If the report is reliable, perhaps Pliny was correct, when 1,900 years ago he emphasized the wealth of India in opal.

From 1890 to the end of 1938, Australia had produced opal worth £1,627,000 in the rough. The 1938 production, largely from South Australia and New South Wales, was worth £8,876, and in 1941 the diggers were said to be busy, so that presumably there is still a small production.

Dr. Henry W. Nichols (see Bibliography) describes a 312-pound block of lapis lazuli exhibited in the Field Museum, Chicago (now Chicago Natural History Museum). It is 2 feet long, 1¼ feet wide, and three-quarters of a foot thick.

In August importers and retailers unabashedly launched Imperial Mexican Jade on the market in a national advertising campaign. The flagrant fake was detected almost immediately, it being proved that the "jade" was merely calcium carbonate ("Mexican onyx") stained green.

Iran and the United States signed a Reciprocal Trade Agreement on April 8, 1943, by which the import duty on cut turquoise into the United States from Iran is reduced from 10 to 5 percent; uncut turquoise has been duty-free for some time. Owing to adequate turquoise deposits, the United States for some years has imported little cut turquoise from Iran.

INSTRUMENT AND CHRONOMETER JEWELS

When the war started, the United States was dependent on Switzerland and France, not only for the synthetic corundum and spinel from which instrument jewels are made but also for their fabrication. Now, the Linde Air Products Co., the Bulova Watch Co., and several smaller companies produce an adequate supply of synthetics, and other firms have adequate fabricating facilities to satisfy the national demand for instrument jewels, which, of course, has been greatly increased by the war. Production increased 370 percent in 1943. War Production Board Order 4717, issued December 23, 1943, eases controls and restrictions on instrument and jewel bearings.

Thus war has introduced in America two more industries—manufacture of synthetics and fabrication of instrument jewels. That of making synthetics presumably should survive after peace is declared.

Small ball bearings have replaced jewels in watches and some instruments, but it is not believed that this substitution will become general.

Out of synthetic sapphire, one American company is now making gages, Diesel injector nozzles, dies for drawing wire from soft metal, and machining tools for soft metals. The gages are of longer life and closer tolerances than those of steel.

Late in the year, the Government of India inquired of Ceylon whether it could furnish 8,000 sapphires and garnets for instrument jewels; further, whether this material could be cut by local lapidaries into instrument jewels. Owing to a shortage of skilled lapidaries, the Colombo jewelers approached were unwilling to attempt to fabricate the jewels.

Organic materials	1574

GENERAL CONDITIONS

Total war still dominated the domestic nitrogen situation in 1943. Nitrogen is essential to the war program, first, in the manufacture of munitions and, second, in the production of food. For the past 2 years supplies of nitrogen have been short, whereas demand is ever-increasing, and to meet current food-production programs the requirements of American farmers for fertilizer nitrogen are at an all-time high.

Before 1943, shortages both for military purposes and for agriculture were evident, but military demands came first. In 1943, emphasis shifted. Decreased ordnance requirements and an increased ordnance supply of anhydrous ammonia made available, for agriculture, increasingly large supplies of ammonia and ammonium nitrate from the munitions plants. The Government encouraged use of this excess supply of ammonium nitrate for fertilizer purposes because of the shortage of nitrogen and the possibility that the shipping normally required for the importation of nitrate of soda from Chile might be conserved. The substitution of ammonium nitrate for sodium nitrate in mixed fertilizers leaves the reduced imports of the Chilean material available for direct application to the soil only.

INORGANIC NITROGEN COMPOUNDS

NATURAL NITRATES

Domestic nitrate deposits.—Although deposits of soluble nitrate minerals are widely distributed in the United States they are too small and too low-grade to serve as a basis for a domestic nitrate industry. Many of the known deposits have been studied, and references to the various published reports are given in the Nitrogen Compounds chapter of Minerals Yearbook, 1942 (p. 1522). There has been no recent output from any of these deposits of natural nitrates, so far as known.

---

[1] Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the United States Department of Commerce.

Chilean nitrate.—Large quantities of natural sodium nitrate and smaller amounts of potassium-sodium nitrate are imported from Chile annually, at present under a wartime subsidy whereby the United States Government absorbs some of the increased costs and prices. These imported sodium nitrates are under allocation, and it is reported that in the year ended June 30, 1943, about 8 percent of the total was applied to war industries and 92 percent to agriculture.

In the fertilizer year July 1, 1942, to June 30, 1943, about 812,000 tons of Chilean nitrate are said to have been used for side and top dressing for crops and a much smaller quantity in mixed fertilizers. In the year begun July 1, 1943, imports of only about 500,000 tons of Chilean nitrate are forecast—a quantity that will be inadequate for full agricultural requirements. Therefore, contrary to the practice in previous years, no nitrate of soda will be allowed in mixed fertilizers during the fertilizer year 1943–44. Its use is restricted to direct application as side and top dressings. Supplies of Chilean nitrate supplemented by synthetic nitrate of soda, equal to about 90 percent of the tonnages used in the previous year, are believed available for this purpose.

Sodium nitrate imported for consumption in the United States, 1939–43

Year	Chile		Total		Year	Chile		Total

SYNTHETIC NITROGEN COMPOUNDS

General.—The general situation with regard to the synthetic nitrogen industry in the United States in 1942 was covered in the Nitrogen Compounds chapter of Minerals Yearbook, 1942 (pp. 1521–1524). The following summary presents the major developments with respect to diverse synthetic nitrogen compounds in the succeeding calendar year, 1943.

Ammonia and its compounds.—The principal uses of ammonia have been military and agricultural; minor quantities are utilized in industry. A surplus of ammonia above military needs became evident in 1943, and restrictions on the use of anhydrous and aqua ammonia in agriculture and industry were relaxed. Ammoniation of superphosphate again became possible.

The domestic capacity for the production of synthetic ammonia has been greatly increased over the pre-war status and now is apparently much greater than any probable post-war demand. Exact figures for the current productive capacity are not yet available. Various estimates have been made, ranging from a general one of twice the maximum pre-war consumption to a recent, more definite statement[2] of 1,322,000 tons.

Synthetic ammonia production from numerous private and Government-owned plants is said to have reached a new high record in 1943. Figures, however, are not available.

Sales of byproduct-coke ammonia liquor (NH_3 content), according to the Bureau of Mines, were 35,674 short tons in 1943 compared with 31,938 tons in 1942. Production likewise was higher but not high enough to compensate for the sharply increased sales, and stocks declined. Considerable quantities of synthetic ammoniating solutions were produced in 1943, some of which were allocated to the fertilizer industry.

General Preference Order M–163, effective June 1, 1942, placed byproduct ammonia under complete allocation control by the War Production Board. General Preference Order M–164, effective the same date, provided for allocation control of synthetic ammonia by the same authority. Both orders remained in force throughout 1943.

Ammonium sulfate, one of the most important agricultural fertilizers and one of the principal sources of nitrogen in mixed fertilizers, is obtained solely as a manufactured product. Virtually all produced is employed for fertilizer purposes. The production of byproduct-coke ammonium sulfate, which constitutes almost the entire production in the United States, decreased from 766,804 short tons in 1942 to 762,645 tons in 1943, but sales increased from 751,914 to 774,834 tons, with a resultant marked decrease in stocks on hand at the end of 1943. Some additional quantities of ammonium sulfate came from other sources. The price of ammonium sulfate per 100 pounds remained at $1.46 f. o. b. Atlantic ports throughout 1943.

War Production Board General Preference Order M–163 of May 30, 1942, effective June 1, 1942, which placed byproduct ammonium sulfate under allocation, remained effective throughout 1943.

Ammonium nitrate was originally produced in large quantities for munitions, but because of decreased ordnance requirements and a larger output substantial supplies were freed by both private and Government-owned plants for fertilizer purposes.

Ammonium nitrate is not a new fertilizer or fertilizer ingredient, but farmers are not generally familiar with it. Consumption of ammonium nitrate, in combination with other materials, in various fertilizers during the years shortly before World War II ranged from a minimum of 1,000 tons in 1932 to 68,000 tons in 1937. Approximately 65,000 tons of ammonium nitrate were used in 1941. The total available supply of ammonium nitrate for fertilizer use in the fertilizer year 1943–44 has been estimated at 345,900 tons. After December 1, 1943, all commercial ammonium nitrate mixtures produced in the United States were to be guaranteed to contain 32.5 percent nitrogen. The pure material contains about 35 percent nitrogen, one-half of which is in the ammoniacal and one-half in the nitrate form.

---

[2] Fortune, Nitrogen: Competition or Not: Vol. 29, No. 2, February 1944, pp. 129–130, 232, 234, 236, 238, 241–242, 244, 247.

Early in 1943 imports of a mixture of ammonium nitrate and limestone produced in Ontario, Canada, were released by the War Production Board for direct application to the soil. Later in the spring ammonium nitrate from certain domestic war plants became available for fertilizer use, and shipments were made from the Tennessee Valley Authority plant at Muscle Shoals, Ala., and a privately owned plant in California. At the end of 1943 ammonium nitrate for fertilizer use was being produced by a number of Government plants in the United States and Canada and by one private plant in California. The Canadian material was handled through private brokers and the Tennessee Valley Authority material by that organization. Effective November 1, 1943, distribution of the ammonium nitrate from the Army's ordnance plants was placed in the hands of the Tennessee Valley Authority for the ensuing 3 months.

The quoted price on the Canadian ammonium nitrate mixture early in 1943 was $56.65 per short ton f. o. b. Port Robinson, Ontario, but in May 1943 was reduced to $47.65. The T. V. A. price of United States ammonium nitrate, November 1, 1943, to January 31, 1944, was set at $49 a ton f. o. b. point of production.

Numerous articles have recently appeared on ammonium nitrate and its use as a fertilizer mixture.[3]

Sodium nitrate.—Little information is available regarding the current production or utilization of domestically produced synthetic sodium nitrate. According to the Department of Agriculture, domestic production and imports to be allocated for direct application are expected to total 805,000 short tons in the year ending June 30, 1944. According to report about 300,000 tons of this available supply is domestic synthetic sodium nitrate.

General Preference Order M–62, effective January 15, 1942, controls the supply and distribution of the synthetic sodium nitrate as well as the imported natural nitrate from Chile.

ORGANIC MATERIALS

An increased demand for organic nitrogen-bearing fertilizers arose late in 1942 because of restrictions in the use of chemical nitrogen. To secure equitable distribution, on May 7, 1943, the War Food Administration issued Food Production Order 12, effective May 1, 1943, banning purchase of these materials by fertilizer manufacturers without prior approval of the director of food production. On June 7, 1943, a revised Food Production Order 12, effective June 1, 1943, to July 1, 1944, was issued. This order limited the quantity that could be so used to 70 percent of that used in 1941–42. About 25,000 tons of organic nitrogen were expected to be available during the period covered by the order, compared with 35,000 tons used in mixed fertilizer in the 1941–42 period.

Calcium cyanamide is not produced in the United States but has been made since about 1910 at the plant of the American Cyanamid Co. of New York at Niagara Falls, Canada, and marketed under the trade name Cyanamid. In 1941, 83,337 tons of cyanamide were imported into the United States for consumption under allocation, principally in Mississippi, Louisiana, and Arkansas.

Urea, a synthetic organic nitrogenous compound containing 46.65 percent nitrogen when pure, now used in considerable quantities in the United States as a fertilizer material, has been produced commercially in the United States only within the last 10 years. The consumption of urea in fertilizer mixtures in the United States increased from 75 short tons in 1925 to over 34,000 tons in 1940. A detailed discussion of this material is given in a recent publication.[4]

GRAPHITE

Production and sales of domestic natural and artificial graphite increased in 1943. The combined total of crystalline and amorphous graphite produced by domestic mines in 1943 was 9,939 short tons, and shipments reached 9,597 tons valued at $903,102, compared with a production of 7,120 short tons and sales of 7,253 tons valued at $401,690 in 1942. Artificial or, more properly, manufactured graphite [2] was produced by the Acheson Graphite Division of the National Carbon Co., Inc., 30 East Forty-second Street, New York, N. Y., from a plant operated at Niagara Falls, N. Y. The uncertainty of foreign shipments prompted the production and stock-piling of domestic natural graphite for use as insurance against the possibility of complete stoppage of imports from Madagascar and Ceylon. However, by the end of 1943, the stocks of strategic graphite in the United States had improved to the extent that domestic plants built with the aid of Reconstruction Finance Corporation funds were shut down. This improvement is reflected in the supplements and amendments to War Production Board Order M–61 relative to the conservation and use of strategic graphite. At the beginning of 1943, all graphite in flake, lump, or chip form of plus 50-mesh U. S. Sieve Series was considered as strategic, and in July the production of graphite crucibles was restricted to those designated as standard by the industry. However, by January 1, 1944, only Madagascar flake graphite of plus 50-mesh screen size was considered as strategic, restrictions on the acquisition of graphite crucibles were relaxed to the point that only inventory control was exercised, and Ceylon lump and chip and domestic flake graphite were removed from the strategic list by the War Production Board.

[1] Less than 1 ton.

Stocks of Madagascar flake and Ceylon lump and chip on January 1, 1943, were, respectively, 3,583 and 2,191 short tons, as reported by the Graphite Branch of the War Production Board. Imports of 5,101 short tons of Madagascar flake plus stocks made a total supply of 8,684 short tons. Consumption of this flake averaged about 400 tons per month, leaving stocks of about 4,200 tons, or about 11 months' supply at the present requirement rate. Imports of Ceylon graphite of all grades decreased markedly in 1943 because of a reduction in requirements and increase in stocks. Imports of 168 short tons of crucible-grade graphite from Ceylon plus stocks made a total supply of 2,358 tons. Consumption of this material averaged about 66 tons per month for the first three quarters and 55 tons for the last quarter of the year, or a total of 759 short tons, leaving stocks at the close of the year of about 1,599 short tons, or about 29 months' supply. Because of a decrease in requirements by gray-iron foundries and increasing stock piles, imports of Mexican amorphous were also lower in 1943 than in the previous year. Stocks of graphite fines represent a 2 years' supply.

Exports of natural graphite, 1939–43, were—1939: 976 short tons, valued at $109,715; 1940: 1,632 tons, $148,639; 1941: 1,723 tons, $166,612; 1942: 4,095 tons, $413,281; and 1943: 3,010 tons, $317,586. The export market includes Canada, England, U. S. S. R., Mexico, India, and Central and South American countries.

Wartime demands have brought mines into production from several new sources, notably South Australia (Port Lincoln), Tasmania, Portuguese East Africa, and India. The industrial research division in India carried out pilot-plant work on obtaining flake graphite by flotation and colloidal graphite from natural-graphite fines.

Metals Reserve Co. prices for domestic flake graphite in 1943 were as follows, in cents per pound: No. 1A, 14; No. 1, 13; No. 1B, 12; No. 2, 11; No. 3, 7; No. 4, 5. Prices for Madagascar and Ceylon graphite in carlots, f. o. b. New York City, duty paid, in 1943 were, in cents per pound: Madagascar No. 1 Flake, 9 to 16; No. 2 Flake, 7 upward; Fines (ground), 55 to 70 percent carbon, 3 upward; Ceylon Lump, 10 to 12; Carbon Lump, 9 to 10; Chip, 7; and Dust, 4 to 5.

Although the quantity of domestic graphite is adequate, the quality is not satisfactory for crucible use, and production costs are greater than for crucible-grade Madagascar and Ceylon material. Therefore, with availability of imported material assured, there is little prospect of post-war market demands for domestic graphite exceeding those of pre-war years.

Figures for total world production are not available. A table covering the period 1915–39 appeared in Minerals Yearbook, Review of 1940 (p. 1414), and the following table includes all production figures from 1937 through 1943 that can be obtained.

World production of natural graphite, 1937–43, by countries, in metric tons [1]

KYANITE, ANDALUSITE, AND DUMORTIERITE

Domestic production and imports of the kyanite-group minerals continued to increase during 1943. Supplies and stocks of imported kyanite were more than adequate for current requirements; therefore, War Production Board Conservation Order M–143 on Indian kyanite, effective May 6, 1942, was withdrawn on November 22, 1943, and inventory control only will be retained to insure a safe supply.

Imports of 514 short tons of sillimanite, a trimorph of kyanite, were received from New South Wales, Australia, in 1943. The material received did not prove satisfactory for heavy-duty refractories, but it seems probable that selective mining of the deposit would produce an acceptable product.

Indian kyanite, in grain sizes from one-fourth inch to 35 mesh, furnishes a coarse-grained product that, when fabricated into a shaped form, meets the requirements of the ceramic and metallurgical industries for heavy-duty refractories. The total supply of Indian kyanite in 1943 was 19,457 short tons. Domestic consumption amounted to 8,416 tons, and 158 tons were reexported to Canada, leaving stocks of 10,883 short tons, of which 5,643 tons were in the hands of the industry and 5,240 tons in the Government stock pile.

Domestic shipments, imports, and stocks of kyanite in the United States, 1940–43

Year	Domestic shipments		Imports from British India		Total new supply		Stocks of Indian kyanite[1]	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1940	4,241	$93,716	7,658	$92,159	11,899	$185,875	(2)	(2)
1941	8,335	175,581	14,285	175,218	22,620	350,799	(2)	(2)
1942	8,708	190,750	6,524	93,743	15,232	284,493	[3] 9,485	$449,317
1943	9,561	238,649	9,972	105,042	19,533	343,691	10,883	515,527

[1] Industry and Government stocks as of Dec. 31, as reported by Miscellaneous Minerals Division, War Production Board.
[2] Figures not available.
[3] As corrected by War Production Board.

Domestic production of refractory-grade kyanite was adequate for current requirements, but a shortage of low-iron, glass-grade kyanite developed because of milling difficulties at the plant of the Yancey Cyanite Co. at Burnsville, N. C., the sole domestic producer. This plant ceased operation on January 5, 1944. The Kyanite Products Corporation, near Farmville, Va., with increased plant production and stabilized manpower, was able to fill all orders for refractory-grade kyanite without reaching maximum production.

The cost of Indian kyanite delivered at Atlantic seaports in 1943 was $54 per short ton. Prices for domestic kyanite, controlled by the Office of Price Administration under Order MPR–327, effective February 17, 1943, were revised upward later in the year. Prices set for the Kyanite Products Corporation of 61 Broadway, New York, N. Y.—$19 per short ton for raw kyanite, 35-mesh, in carlots to $37.50 for 325-mesh material, less than carlots, in 100-pound bags, and $26.50 per short ton for calcined kyanite, 35-mesh, in carlots, to $42.50 for 325-mesh material, less than carlots, f. o. b. Cullen or Pamplin, Va.—were raised $5 per ton for all classes in amendment 4 of this order, effective November 2, 1943. The ceiling price for glass-grade kyanite produced by the Yancey Cyanite Co. (Asheville, N. C.), fixed at $40 per ton on February 17, 1943, was raised to $45 per ton and later was lifted entirely.

Production of andalusite at White Mountain, Mono County, Calif., by Champion Sillimanite, Inc., Merced, Calif., decreased slightly from the 1942 level; but production of dumortierite at Oreana, Pershing County, Nev., by the same company—the only domestic producer of either mineral in 1943—increased. This material was shipped to the parent firm, Champion Spark Plug Co., Detroit, Mich., for use in spark-plug cores and other electrical porcelains.

LITHIUM MINERALS

Although production of lithium minerals and compounds in 1943 was greater than in any preceding year since 1920, it was not sufficient to keep pace with demands. Shipments of spodumene were greater than the total sales of lithium minerals in 1942, but the production of lepidolite, amblygonite, and dilithium sodium phosphate decreased.

The shortage of spodumene concentrates that developed in 1942 because of inadequate milling facilities continued through 1943. Although the Solvay Process Co. plant at Kings Mountain, N. C., began operations on May 17, unexpected difficulties in milling practices arose, and problems of priorities for steel and machinery slowed the rebuilding of the Black Hills Tin Co. plant at Tinton, S. Dak. However, there has not been a shortage of ore. The requirements for lepidolite for use in the manufacture of boron silicate glass for electronic tubes and high-pressure boiler gages also exceeded domestic production, and it became necessary to import spodumene and lepidolite. Imports amounted to 832 short tons—276 tons of spodumene from Brazil, 166 tons of spodumene from Argentina, and 390 tons of lepidolite from Southwest Africa.[3]

Shipments of lithium compounds from mines in the United States, 1939–43

Year	Short tons	Value
1939	1,990	$97,000
1940	2,011	80,679
1941	3,832	115,718
1942	5,405	$243,516
1943	8,155	314,660

However, by December 1943 the Kings Mountain plant was operating at near maximum level, and the Black Hills plant began production on February 1, 1944. The decrease in production of lepidolite, amblygonite, and dilithium sodium phosphate may be attributed in part to the emphasis placed by the War Production Board upon the production of spodumene. As it will take some time to increase domestic production to meet requirements, additional imports of lepidolite will be required in 1944.

Prices for lithium ores produced in the United States for sale on the open market, as quoted by E&MJ Metal and Mineral Markets, in 1943 were as follows: Spodumene $5 per 20 pounds of contained lithia (Li_2O), 6 percent minimum, $30 per short ton, in carlots; amblygonite, 8 to 9 percent (Li_2O), $40 to $50 per short ton, f. o. b. mine; and lepidolite, 3 percent (Li_2O), $24 to $25 per short ton, f. o. b. mine.

---

[3] Reported by the War Production Board, Statistics Division, Materials Branch; checked by War Shipping Administration.

Although the increased demand for lithium minerals and compounds may be attributed to their use as bases of many essential war products, the majority of these products will have a post-war use, and it is reasonable to believe that post-war requirements for these minerals will be larger than in 1939, a peak pre-war year.

MINERAL EARTH PIGMENTS AND MANUFACTURED IRON OXIDE PIGMENTS

[Prepared by Charles L. Harness]

Sales of natural and synthetic iron oxide-containing pigments increased 3 percent in quantity in 1943 over 1942. The increase, in view of negligible civilian construction activity, pointed to expanded military uses. Iron oxide pigments find extensive application in flat camouflage paints for trucks, "jeeps," artillery, and aircraft. Much yellow iron oxide is compounded with chromic oxide to form the well-known olive-drab shade. Paint for the shipbuilding program required large quantities of both natural and synthetic red iron oxide in 1943.

Statistics of production and foreign trade are presented in the following tables:

Natural mineral pigments and manufactured iron oxide pigments sold by processors in the United States, 1942–43, by kinds

Pigment	1942		1943	
	Short tons	Value	Short tons	Value
Mineral blacks	2,229	$83,558	3,428	$104,369
Precipitated magnetic blacks	2,244	378,395	1,602	271,516
Natural brown oxides (metallic browns)	7,839	334,445	7,114	337,514
Vandyke brown (finished pigment) and sap brown	208	27,915	899	154,845
Pure browns (96 percent or better iron oxides)	1,085	191,248	818	163,122

[1] Less than 1 ton.

The war has cut off or curtailed imports of many foreign earth pigments, including Turkey umbers, Italian siennas, French ochers, and Persian and Spanish red oxides, and for most products the domestic pigment industry has supplied replacements that are as good as or better than the foreign pigments, costs and quality considered. Possible exceptions are Persian and Spanish red oxides, for which no substitute seems to have proved completely satisfactory. There is every indication that the domestic pigment industry will supply most post-war domestic earth-pigment markets formerly dominated by foreign products.

Prices of finished earth pigments, which are quoted in cents per pound, were generally unchanged during the year, according to the Oil, Paint and Drug Reporter. Precipitated magnetic blacks, in barrels, less carlots, works, were quoted at 8½; metallic browns were 2½ in barrels; Vandyke brown sold at 9 and sap-brown crystals at 12; synthetic browns, 12; synthetic red iron oxides, 9¾; Venetian reds, 2.2 to 4, depending on the iron oxide content; natural yellow oxides, high-iron, 5; synthetic iron oxide yellows, 7.1; domestic French-type ochers, 3.45; burnt siennas were quoted over a range of 3¾ to 10¾;

Italian type siennas over a range of 3¼ to 16¾, prices increasing later in the year; raw siennas ranged from 4 to 10; and umbers were quoted at 3⅜ to 5⅞, depending on quality and point of purchase.

MINERAL WOOL

Mineral-wool production in 1943 reached 551,524 short tons valued at $43,670,710, an increase of $10,863,902 in value and approximately 33,000 tons in quantity over the 1942 total. Sales of home insulation increased and those of industrial insulation decreased from 1942 totals. Production in 1943 came from 40 companies operating 53 plants in 19 States, compared with 41 companies operating 52 plants in 18 States in 1942, the first year for which statistics on mineral wool were collected by the Bureau of Mines.

Production of mineral wool in the United States, 1942–43

[1] Linear feet; approximately 5,500 short tons.

It seems probable that the increase in home insulation may be attributed largely to the Government-sponsored program for insulating homes to conserve fuel, and the decrease in industrial insulation to the wartime conservation of materials for construction or expansion of industrial plants. As part of the fuel-saving program, the Bureau of Mines issued an information circular on the conservation of fuel in industrial plants by means of insulation,[4] and the Industrial Mineral Wool Institute, 441 Lexington Ave., New York, N. Y., prepared a heat- and power-conservation manual. In September, the National Bureau of Standards and the Industrial Mineral Wool Institute proposed commercial specifications for the use of mineral-wool blankets, blocks, pipe covering, and insulating cement for heated surfaces. They have been accepted as Commercial Standard CS 117–44 for high-temperature installations effective from May 25, 1944.

---

[4] Bowles, Oliver, Industrial Insulation with Mineral Products: Bureau of Mines Inf. Circ. 7263, 1943, 17 pp.

The Office of Price Administration, on September 16, 1943, under amendment 3 of Order A–2 of Maximum Price Regulation 188, provided for an adjustment in maximum prices of producers of mineral wool. The new provision permits the granting of relief to cover total manufacturing costs for manufacturers who are unable to maintain or expand production under existing maximum prices in areas where there is a general shortage and where operation of all plants in the area is necessary to prevent an increase in the price to the consumer. Prices in 1943, per short ton, in carlots f. o. b. plant, were $30 for loose and $45 for granulated wool.

Although conservation of fuel during wartime has been instrumental in increasing the production and sales of mineral wool, insulation is a permanent economy and an effective means at all times of overcoming the discomforts of both heat and cold. It seems probable, therefore, that the post-war market for mineral-wool products will be larger than during the years immediately preceding the war.

MONAZITE

Imports of monazite sands in 1943 from Brazil and India, currently our only source, increased 12 percent in quantity and 24 percent in value compared with 1942. Domestic consumption decreased, and stocks increased during 1943. At the request of the Army and Navy, the Procurement Division of the Treasury Department in 1943 purchased abroad 3,000 long tons (3,360 short tons) of monazite sand for a Government stock pile, and 1,112 short tons of this amount was imported during the year.

The wartime requirements for the rare-earth oxides contained in monazite have been stabilized, and our position in relation to stocks and supplies is favorable.

Indian monazite is better cleaned and graded than the Brazilian. Although the monazite content of the Brazilian sands is higher than that of the Indian, the thorium content is lower. The following quoted prices are nominal: $42.50 per long ton, f. o. b. India, plus $24 ocean freight to Baltimore, and $64 per metric ton, f. o. b. Brazil, plus $17 ocean freight to Baltimore.

Commercial production of cerium alloys from monazite deposits in Australia was reported for the first time in 1943.

Monazite sand and other thorium ore [1] imported for consumption in the United States, 1939–43, by countries

Country	1939		1940		1941		1942		1943	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
Brazil	54	$1, 516	201	$7, 440	734	$25, 240	1, 346	$62, 555	1, 911	$88, 548
India and Dependencies	1, 336	46, 753	2, 766	92, 387	2, 714	82, 068	3, 052	112, 928	3, 033	128, 379
Netherlands Indies	170	3, 747								
United Kingdom [2]									36	3, 553
	1, 560	52, 016	2, 967	99, 827	3, 448	107, 308	4, 398	175, 483	4, 980	220, 480

[1] Quantities are gross weight; monazite content not reported.
[2] United Kingdom of Great Britain and Northern Ireland.

Many of the uses for rare earths contained in monazite that have been developed during the war will have post-war applications. It is possible, therefore, that the peacetime market, although not large, will be more stable than in pre-war years.

OLIVINE

Shipments of olivine from North Carolina in 1943 decreased to 5,415 tons valued at $48,633, as against 5,739 tons valued at $45,201 in 1942, the peak year of domestic production. The entire output in 1943 was consumed in refractories.

Experimental work on the direct reduction of olivine in an electric furnace with the addition of theoretical amounts of MgO to obtain essentially pure crystalline forsterite for use in the roofs of open-hearth furnaces was performed in the Electrotechnical Laboratory of the Bureau of Mines.[5] The addition of MgO completely eliminated the impurities and increased the high-temperature load-bearing strength of the product. The Tennessee Valley Authority developed a new use for olivine.[6] By fusing a mixture of rock phosphate and olivine in the proportions 0.46 pound olivine to 1 pound phosphate rock, a fertilizer is produced containing 22.8 percent total P_2O_5, of which 21.4 percent is citrate soluble and thus available for plant food. Prices for crude olivine f. o. b. North Carolina were quoted at $5 to $7 per short ton: ground olivine, 200-mesh, $17; and 20-mesh to dust, $12.

There is little prospect of post-war market demands for olivine exceeding those of pre-war years for its established uses, but the new uses now under investigation have additional possibilities.

PIEZOELECTRIC QUARTZ

Piezoelectric-grade quartz, a necessary component part of radio transmitting and receiving sets, detection devices, long-distance telephone transmission lines, and various precision instruments, remains near the top of the list of strategic and critical minerals. Domestic sources supplied a small tonnage for the first time since World War I, but we are still dependent almost exclusively on Brazil.

Imports of quartz for piezoelectric use in 1943 reached 1,678 short tons valued at $11,370,803, compared with 1,306 tons valued at $8,987,108 in 1942. Except for 680 pounds received from Guatemala and 585 pounds from Colombia, the entire quantity was received from Brazil. Domestic production of 2.9 tons, valued at $25,598, added to imports makes a total new supply of 1,680.9 tons. Domestic production of piezoelectric devices in 1943 amounted to 14,011,677 small oscillators, 8,474,523 large oscillators, 65,595 telephone resonators, and 24,355 units of detection equipment.

Specifications for piezoelectric quartz drawn up in 1942 by the National Bureau of Standards have changed frequently as a result of advances in technology and experience. In March 1943, specifications were revised to include fragments ranging from 100 to 200 grams in weight, 45 percent usable, and quartz containing blue needles. In January 1944, the specification for usable quartz in pieces weighing 200 grams or more was liberalized to include quartz containing moderate quantities of hard and soft blue needles, some color, fine bubbles, and inclusions; also, the 100 to 200 gram-weight material was classed as radio grade only if 80 percent appeared usable when inspected without instruments.

LIST 3. SMALL MATERIAL (MUST BE FACED) [2]

Weight class	Weight, pounds	Grade 1		Grade 2	
		45–100 percent 14L	45–100 percent 14S	45–100 percent 24L	45–100 percent 24S
1–2	0.22–0.44	$2.40	$2.00	$2.00	$1.60

[1] Purchase is made through Metals Reserve Co., a Government agency, on the basis of inspection at the Bureau of Standards. Prices given are price per pound, f. o. b. Bureau of Standards, Washington, D. C. In the symbol 13, 1 stands for grade 1, 3 stands for 30–45 percent usable. Weight class 2–3 means 200 to 300 grams, 7–10 means 700 to 1,000, and 100- means over 10,000 grams, or over 22 pounds.

[2] Small material, 100–200 grams, is separated on the basis of shape into long and short. Thus, 14L means first grade, 45–100 percent usable, and long shape.

The average number of oscillator plates obtained per pound of usable quartz increased from 9.5 in 1942 to 16.3 in 1943 as a result of an increase in cutting efficiency and a change in the design of oscillators so that smaller plates could be used. Discarded material on hand was reinspected, and 650,000 pounds of usable quartz were recovered. The War Production Board, under Conservation Order M–146 and its amendments, retains control of importation, stocks, sales, and transfers of piezoelectric quartz.

The consumption of piezoelectric quartz has expanded rapidly during the present war because of its importance in communication and detection devices. However, the same use pattern will continue in peacetime; and, with the advances made in communication technique during the war, it seems probable that post-war consumption will exceed that of the years immediately preceding the war.

SERPENTINE

Serpentine, a hydrous magnesian silicate that usually occurs as an alteration product of dunite, has again attracted attention among the industrial minerals. In 1943, the International Minerals & Chemical Co. (20 North Wacker Drive, Chicago, Ill.) used a deposit near Augusta, Ga., to make Epsom salts, and the Idaho-Maryland Mines Corporation of Grass Valley, Calif., and H. G. Wildman of Montreal, Canada, have developed processes utilizing serpentine to obtain magnesium. The Idaho-Maryland Corporation, primarily a gold-mining company, used serpentine that overlies the gold-bearing rock; and the Wildman process, which has been patented, uses serpentine from the waste piles at the asbestos mills near Thetford Mines, Quebec. These processes, however, have not progressed beyond the experimental or pilot-plant stage, and, unless they have definite cost advantages, it is unlikely that serpentine will become an important source of magnesium or magnesium compounds in the post-war markets.

STRONTIUM MINERALS

[Prepared by Charles L. Harness]

Tracer bullets and signal flares continued to provide a strong demand for domestic celestite (crude strontium sulfate) in 1943; also, low-grade celestite was used in oil-well drilling muds, substituting foı scarce barite. Shipments of celestite by producers in 1943 totaled 7,566 short tons valued at $114,526, compared with 4,041 tons valued at $55,529 in 1942. The figures include both chemical and nonchemical grades.

The principal domestic producers were the Pan-Chemical Co., 205 First National Bank Building, Pomona, Calif., deposit in the Fish Mountains of Imperial County, Calif.; the Milwhite Co., Inc., Cotton Exchange Building, Houston, Tex., deposit near Blanket, Brown County, Tex.; and Bennett-Clark Co., Inc., Box 951, Nacogdoches, Tex., deposit in Nolan County, Tex. Smaller producers and shippers were Robert I. Carr, Nashville, Ark., deposit at Dierks, Ark.; Inorganics, Inc., Knoxville, Tenn., deposit at Jamestown, Tenn.; Xact Products Co., 905 State National Bank Building, Houston, Tex., deposit at Del Rio, Tex.; and William G. Pearson, San Diego, Calif. (location of deposit not stated).

Consumption of celestite in the manufacture of strontium chemicals in 1943, was 13,387 short tons. Stocks of celestite, intended for chemical use, on December 31, 1943, were 13,732 tons, held mostly by Metals Reserve Co. Imports of celestite in 1943 were 16,881 short tons valued at $249,580, principally from Mexico, compared with 10,358 short tons valued at $144,848 in 1942.

Post-war prospects for the domestic celestite industry are negligible, because when prices drop to peacetime levels, which may approximate

$12 to $15 a short ton, c. i. f. eastern seaboard, it is unlikely that suppliers in California and Texas can compete with producers in England, Spain, and Mexico.

Prices of lump celestite remained at $30 to $35 a short ton laid down in the Philadelphia area, the same as in 1942.

TOPAZ

Production and sales of topaz in 1943 by the United Feldspar & Minerals Corporation, of Spruce Pine, N. C., from the Brewer mine near Kershaw, S. C., exceeded the 1942 figures. The topaz was used in refractories, steel mills, and in the manufacture of boro-silicate glass. In all these applications, it served chiefly as a substitute for more critical minerals, and, with the exception of the manufacture of glass, it did not progress beyond the experimental stage.

VERMICULITE

Sales of cleaned and screened vermiculite in 1943 decreased 11,203 tons (19 percent) from the all-time high of 1942, but the value increased $151,664 (47 percent).

The decline in quantity was due chiefly to a landslide at the mine at Libby, Mont., operated by the Universal Zonolite Insulation Co. (135 S. LaSalle St., Chicago, Ill.), the predominant producer, which curtailed production during the first half of the year. Other factors responsible for the decrease in production were manpower shortages at several mines and curtailed requirements for lightweight aggregate because of a reduction in building construction during the year. The average value per ton of the mine product at Libby, Mont., virtually doubled that of 1942, which accounts for the decided increase in total sales value. A review of the domestic deposits, including a description of their development, has been published recently.[7]

Production figures for domestic mines from 1939 through 1943 follow. Commercial production of vermiculite began in 1915, but the yearly output was reported as part of the mica total, or under the heading "Minerals Allied to Mica," until 1924. A table covering the period 1924–39 appeared in Minerals Yearbook, 1940.

Screened and cleaned vermiculite sold or used by producers in the United States, 1939–43

Year	Short tons	Value	Year	Short tons	Value
1939	21,174	$174,587	1942	57,848	$319,931
1940	22,299	137,698	1943	46,645	471,595
1941	23,438	125,444			

Virtually all vermiculite that enters the domestic market is cleaned and screened at the mine; some is exfoliated by the producers, or it may be sold to a processor for exfoliation. Screened vermiculite was sold to processors at $8 to $12 a short ton, f. o. b. mine. The exfoliated material was quoted at 70 cents to $1.25 a bag, each bag containing 4 cubic feet weighing 25 pounds, or $56 to $100 a short ton, f. o. b. works. Loss per ton between the raw material and the exfoliated product is about 10 percent. Assuming an average value of $75 a ton for exfoliated vermiculite, the value of sales in 1943 would be approximately $3,250,000.

---

[7] Gwinn, G. Richards, Marketing Vermiculite: Bureau of Mines Inf. Circ. 7270, 1944, 15 pp.

Commercial production of vermiculite has been reported from Russia, South Africa, and Australia. Only the Russian and South African deposits are worked commercially. The Australian deposits are in process of development within the scope of the Australian market.

It seems probable that the domestic post-war market for vermiculite will be larger than in the years immediately preceding the war but somewhat below the 1942 peak.

WOLLASTONITE

A small tonnage of wollastonite, a calcium metasilicate ($Ca\ SiO_3$), was mined in 1943 from a deposit near Willsboro, Essex County, New York. It is used in the preparation of coated welding rods and in flux-shielded arc welding, the latter being a process developed by General Electric welding engineers. It also possesses satisfactory properties for use as a plastic filler, linoleum filler, ingredient for non-shrinking tile bodies, and as a scavenger in alloy-steel manufacture.[8]

The industrial uses for wollastonite are largely in the experimental stage; however, there are possible post-war markets if production costs are favorable.

INTRODUCTION

The mineral industries of the United States employed fewer men in 1943 than in 1942 and thus continued the downward trend in employment that set in following 1941. A fractional decline occurred also in the number of man-hours worked, but the volume of work as thus measured remained well above the level in 1941. Iron-ore mining and the manufacture of byproduct coke appear from early reports to have increased the number of their employees. Increases in man-hours worked were indicated for coal mines, iron-ore mines, byproduct coke ovens, and smelters. Considering all mineral industries as a group, reports thus far received from operating companies show a reduction of 9 percent in number of employees and less than 1 percent in the number of man-hours worked. Of 22 groups for which separate figures were compiled, 18 had fewer employees and 15 fewer man-hours worked in 1943.

Accidents chargeable to the hazards of the work on which the employees were engaged were responsible for 1,813 deaths and 90,927 nonfatal lost-time injuries among the workers. These figures are estimated from reports from those companies that have thus far replied to Bureau of Mines inquires concerning operations during 1943. The figures reflect a fatality rate of 1.18 per million man-hours of work performed during the year, a rate more favorable than that of 1.21 for 1942, and they also indicate a nonfatal-injury rate of 59.11, which also compares favorably with the previous year's injury rate of 61.24.

The mineral industries, when considered as a group, thus had a more favorable accident record in 1943 than in 1942. Among the branches of the industries that contributed to the improvement, at least as far as nonfatal injuries are concerned (and these comprise by far the largest class of accidents), may be mentioned the anthracite mines of Pennsylvania, bituminous-coal mines in the Nation as a whole, miscellaneous-metal mines, slate quarries, and metallic-ore concentrating plants. These classes of operations must be credited with the net over-all reduction in the injury rate in 1943.

Although no data are available to account fully for the large reduction in the number of men employed in 1943, it is believed that among the principal causes of the reduction were the enlistment or draft of many men from the mining and allied industries into the armed forces of the United States and the transfer of other men to various war-supporting industries, although mining itself—especially those branches engaged in the production of minerals vitally or critically needed in the prosecution of the war—constitutes a war-supporting industry. The losses of men, however, were somewhat lessened in their damaging effect upon the prosecution of the war by the fact that the men who remained in the mines were employed at their jobs for a greater number of days during 1943 than during the previous year. The over-all average of 277 workdays per man in 1943 represented a gain of 17 workdays per man over the working time of the preceding year. Measured in hours, the gain for the average worker was about 178 hours. The gain was more than this for several branches of mining—for example, bituminous-coal mining, in which the average worker gained 23 days or 240 hours in 1943 over the period of his employment in 1942.

Number of men employed[1] in the mineral industries of the United States, 1941–43

	1941	1942	1943[2]
Coal mines:			
Bituminous[3]	457,737	448,797	[3] 409,000
Pennsylvania anthracite	88,948	82,064	76,000
	546,685	530,861	485,000
Metal mines:			
Iron	25,870	28,956	29,300
Lead-zinc (Mississippi Valley)	8,634	9,555	9,100
Copper	21,576	23,222	22,600
Gold and silver lode mines (including lead, zinc, and copper, except as listed above)	38,235	23,156	15,300
Gold placer mines	13,368	8,417	2,400
Miscellaneous (tungsten, manganese, etc.)	6,614	8,034	8,100
	114,297	101,340	86,800
Nonmetallic-mineral mines	11,088	11,233	9,900
Quarries:			
Cement	28,859	30,235	26,800
Marble	2,693	2,205	1,600
Slate	2,845	2,284	1,700
Traprock	3,029	3,114	2,600
Granite	7,830	6,307	5,300
Sandstone	3,180	2,840	2,800

	22,641	23,909	25,500
Metallurgical plants:			
Ore dressing	14,807	13,693	13,500
Smelters	22,003	20,636	20,400
Auxiliary works	17,539	16,825	17,000
	54,349	51,154	50,900
Grand total	835,183	802,767	732,600

[1] Figures represent summation of reports for individual mines showing daily average number of employees at each mine on days when mine was in operation.

[2] Subject to revision.

[3] The estimated average number of men "at work and exposed to mining hazards" in bituminous-coal mines was 409,000 in 1943. This figure is used throughout this chapter on employment and accidents. The estimated average number of men "on the rolls during days of operation" was slightly higher, that is, 428,000.

[1] Subject to revision.

EMPLOYMENT AND ACCIDENTS

BITUMINOUS-COAL MINES

Employment.—The needs of the armed forces, munitions plants, and other war-supporting industries combined to draw men away from coal mining (also a war-supporting industry) in 1943, so that a large reduction in number of employees in coal mines was revealed by reports from operating companies to the Bureau of Mines. Although reports have not been received from all companies, and will not have been received from some companies until late in 1944, available reports indicate that the number of employees engaged in mining bituminous coal dropped from 448,797 in 1942 to approximately 409,000 in 1943, a decrease of 9 percent. Production of coal is estimated at 593 million tons, an increase of about 2 percent over the output of the previous year and more than the output of any year in the entire record of mining in the United States. The mines were active about 267 days per man, as compared with 244 days in 1942. Man-hours of work during the year are estimated at nearly 789 million, to which might be added approximately 14 million man-hours to cover an estimate of the amount of "travel time" in November and December—that is, time required for the underground employees to travel from the mine entrance to their working places at the beginning of the shift and return to the mine entrance at the close of the day's work. An element of error is probably involved in the estimate of 14 million hours of "travel time" as the item was not specifically reported by the companies. Instead, some companies reported 8¼ hours, and others reported 8¾ hours as the length of shift during the last 2 months of the year; nearly all companies reported 7 hours per shift for months previous to November. From these reports, working time plus travel time is estimated at more than 802 million man-hours.

Accidents.—From reports so far received from the mining companies it is estimated that 1,248 men were killed and 53,000 men injured by accidents at the mines during 1943. The fatality rate was 1.58 per million man-hours of "working time" or 1.56 per million hours of total estimated time at the mines. As the fatality rate during the year 1942 was 1.61, the rate for 1943 reveals an improvement as far as fatal accidents are concerned. The estimated number of nonfatal injuries during 1943 reflects a rate of 67.21 per million man-hours of work and 66.06 per million man-hours if travel time is included. Either of these rates likewise reflects a fractional reduction when compared with a finally reported rate of 68.83 for 1942.

The year was marked by seven major disasters throughout the bituminous fields, in which 161 men lost their lives—148 in explosions of gas or dust and 13 in a mine fire. During 1942 there were also seven major disasters, in which 132 men lost their lives—127 from explosions of gas or dust and 5 in a surface haulage accident.

Detailed causes of the more than 54,000 fatal and nonfatal injuries during 1943 are not yet available and will not be until all reports are received from the operating companies. However, a study of coal-mine accident records over a period of recent years shows the probable cause-distribution of both fatal and nonfatal accidents that prevailed in 1943. In numerical importance, the principal causes of fatal accidents were falls of roof or face, haulage, gas or dust explosions, electricity, and machinery. The main cause of nonfatal accidents were falls of roof or face, haulage, handling materials, hand tools, and machinery. These causes covered about 87 percent of the fatalities and about 76 percent of the nonfatal injuries that were disclosed by final figures for 1942.

ANTHRACITE MINES

Employment.—This branch of the mineral industries includes operations engaged in extraction and preparation, by screening and sizing, of anthracite from virgin deposits, breaker waste, dredging culm banks, and strip-pit and underground mines. Figures are confined strictly to

Pennsylvania. During 1943 the production of anthracite is estimated at 59 million short tons, exclusive of about 1½ million tons of so-called bootleg coal, as reports of accidents or employment from mines that produce such coal are not available. The industry employed approximately 76,000 men in 1943 according to reports available at present. These men worked approximately 146 million hours in and about the mines, breakers, preparation plants, washeries, and strip pits. Seven hours was the standard shift until November, when a 7¼-hour shift was begun. The mines were operated about 272 days during the year compared with 239 days in 1942, a gain of 33 days per man.

Accidents.—Accidents during 1943 killed 228 men, 2 more than reported in 1942. The number of nonfatal injuries decreased slightly, the estimate for 1943 being 15,500 compared with 16,371 reported for the previous year. In relation to the number of man-hours of work, the record for 1943 was more favorable, as the fatality rate was 1.56 (tentative) as against 1.64 for 1942, and the rate for nonfatal injuries was 106.16 (tentative) as against 119.01 per million hours worked.

The anthracite mines of Pennsylvania have to their credit an outstanding safety record regarding freedom from major disasters, that is, disasters in which five or more lives are lost. Reports show that no major disaster of any kind occurred during the period from June 3 1938, to September 23, 1943, a period of 5 years, 3 months, and 20 days'

IRON-ORE MINES

Employment.—Reports so far received indicate a continued increase in number of men employed and volume of work performed at iron-ore mines in 1943. Tentative figures reveal an employment of approximately 29,300 men compared with 28,956 in 1942. Man-hours of work performed likewise increased to more than 67.8 million, a gain of about 1 percent over the previous year. The number of workdays per employee increased only slightly in 1943.

Accidents.—According to present information, there were fewer fatalities but more nonfatal injuries in 1943 than in 1942. About 45 men were killed last year compared with 56 in 1942. Reports for 1943 also indicated that 1,620 men sustained injuries which caused them to lose time from their work. The combined accident-frequency rate in 1943 was about 24.56 per million man-hours, which was only a fraction higher than the rate of 24.41 for 1942. These rates include a fatality rate of 0.66 in 1943 and 0.84 in 1942.

COPPER MINES

Employment.—Employment at copper mines in 1943, although higher than that for 1941, dropped below the 1942 figure. According to available reports, the number of mine workers was approximately 22,600, a decrease of 3 percent below 1942, although an increase of 5 percent over 1941. Man-hours worked at the mines fell to 58.7 million from 60.4 million in 1942, but were more than the 55.1 million worked in 1941.

Accidents.—Present estimates of accidents show an increase in 1943. The number of deaths was 73 and the number of injuries 3,200. An explosion of dust and sulfur fumes at the Boyd mine of the Tennessee Copper Co., which caused the death of 9 men, was partly responsible for the increase in fatalities. These figures represent a fatality rate of 1.24 and an injury rate of 54.51 per million man-hours worked compared with a fatality rate of 0.83 and an injury rate of 49.43 for 1942.

LEAD-ZINC MINES (MISSISSIPPI VALLEY STATES)

Classification.—Included in this group are mines that produce lead and zinc in the Mississippi Valley States, principally Oklahoma, Missouri, and Kansas, known as the Tri-State area; also included are fluorspar mines in Kentucky and Illinois, as similar accident conditions prevail in the two classes of mines in the States named. This procedure not only permits the publication of separate figures for Kentucky and Illinois but also maintains unbroken a statistical series in Bureau of Mines accident records that extends back to 1911.

Employment.—The number of men employed and the number of man-hours of work performed in 1943 declined in comparison with 1942 but remained at a higher level than in 1941. Incomplete returns indicate a total of more than 9,100 employees, a decrease of 5 percent from 1942. The total volume of employment measured in man-hours decreased from 21.1 million in 1942 to 19.6 million in 1943, a loss of 7 percent.

Accidents.—Tentative figures based upon reports now available indicate an accident-frequency rate in 1943 of 57.24 deaths and injuries per million man-hours of work performed, a slight increase over the rate of 54.15 for 1942. Accidents during 1943 included 22 deaths and 1,100 injuries. Eight men were killed by a cave-in at Shullsburg, Wis., on February 9, 1943.

GOLD AND SILVER MINES (LODE AND PLACER)

Classification.—This group includes not only mines that were operated chiefly for the gold or silver content of their ores but also lead and zinc mines located outside of the Mississippi Valley States and mines that produced some copper but that were operated chiefly because the ore contained metal other than copper.

Employment.—Employment at both lode and placer mines showed a continued sharp decline in 1943 from 1942. The war program resulted in an order by the War Production Board in 1942 that excluded gold and silver mines from the priority benefits of Preference Rating Order P–56; the higher scale of wages paid by defense industries caused a general exodus from gold and silver mines; and the needs of the armed forces likewise contributed to the manpower shortage. These and other economic factors accounted for the sharp decline in the number of men employed and the volume of labor performed in 1943. The group as a whole, upon a basis of preliminary returns, employed about 17,700 men in 1943; 15,300 represented the number of workers at lode mines and 2,400 those at placer operations. Lode mines in 1942 employed 23,156 men and placer mines had 8,417 workers. Man-hours of employment in 1943 totaled 29.7 million at lode mines and 3.5 million at placers. There was therefore a decline of about 44 percent in the total number of men employed and about 45 percent in the total volume of labor performed.

Accidents.—As estimated for 1943, the accident-frequency rate was less favorable than that revealed by final figures for 1942 for both lode and placer mines. The tentative rate for 1943, covering fatal and nonfatal accidents, was 104.37 per million man-hours worked compared with a final rate of 91.90 for 1942; the rate for placer mines was 40.00 compared with 36.92 in 1942; the rate for lode mines was 111.95 in 1943 and 105.75 in 1942. It is estimated that 25 men were killed and 3,440 injured by accidents in 1943.

MISCELLANEOUS METAL MINES

Classification.—Included in this group are all mines engaged in the production of metallic ores, exclusive of gold, silver, copper, lead, zinc, and iron; these mines yield such strategic and critical war minerals as bauxite, manganese, chromite, tungsten, mercury, and molybdenum, as well as various other minerals.

Employment.—Company reports to the Bureau of Mines now on hand show that this group as a whole employed about 8,100 men in 1943 compared with 8,034 in 1942. Man-hours of employment decreased from 17.9 million in 1942 to 17.2 million in 1943.

Accidents.—The safety record of the miscellaneous metal-mine group as estimated for 1943, was more favorable than in 1942. The accident-frequency rate per million man-hours of employment decreased from 88.34 in 1942 to approximately 65.23 in 1943, the lowest rate since 1938. Accidents during 1943 caused 22 deaths and 1,100 nonfatal lost-time injuries among the workers, according to reports thus far furnished to the Bureau of Mines by the operators of the mines.

NONMETALLIC-MINERAL MINES

Classification.—This group includes mines that yield any kind of nonmetallic mineral except coal, stone sand, gravel, and clay; therefore, it includes mines that produce phosphate rock, gypsum, magnesite, barite, sulfur, feldspar, rock salt, mica, and many other minerals.

Employment.—Preliminary reports reveal that over 9,900 men were employed in 1943, a decrease of 12 percent from the 11,233 men employed in 1942. Man-hours of employment amounted to approximately 23.4 million, a loss of 6 percent from 1942.

Accidents.—Although final figures are not available present reports for 1943 indicate that 15 men were killed and 1,200 were injured by accidents during the year. The accident-frequency rate per million man-hours was 51.92 in 1943 compared with the slightly lower rate of 51.88 for 1942.

CEMENT MILLS AND QUARRIES

Employment.—Approximately 26,800 men were employed in the cement industry (quarries and mills) in 1943, a decrease of 11 percent from 1942, when a total of 30,235 men was employed. These men worked an estimated 61.7 million man-hours, a decrease of 13 percent from the number of hours worked during the preceding year. The volume of work reported for 1943 indicated an average of 299 days per employee, a loss of 15 days per employee from the record of 1942.

Accidents.—Despite decreased employment the number of accidents increased. The number is estimated at 830 for nonfatal injuries and 23 for fatalities compared with a final count of 787 injuries and 46 fatalities in 1942. The tentative fatality rate was 0.37 and the nonfatal-injury rate 13.45 per million man-hours of employment compared with final rates of 0.65 and 11.07 in 1942.

MARBLE QUARRIES

Employment.—The decline in employment at marble quarries in 1942, as reported a year ago, continued through 1943. Approximately 1,600 men were employed and 3.6 million man-hours were worked, a decrease of 27 percent in the number of employees and 19 percent in the number of man-hours of exposure to occupational risk. The number of man-days of work performed during 1943 represented an average of 269 workdays per man; an increase of 22 days over 1942.

Accidents.—No man lost his life by an accident at a marble quarry in 1943. Nonfatal injuries numbered 210 and resulted in a rate of 58.33 injuries per million man-hours. This rate compares unfavorably with the nonfatal-injury rate of 38.55 in 1942. However, the fatality-free record of 1943 compares favorably with the fatal-accident record of 1942, as accidents during the latter year resulted in the death of two men.

SLATE QUARRIES

Employment.—It is estimated that 1,700 men were employed in slate quarries in 1943, a decrease of 26 percent from the number employed in 1942. Man-hours of employment totaled 3.5 million, a decrease of 22 percent. An average of 246 workdays per employee indicated an increase of 15 days per employee over the previous year.

Accidents.—Preliminary reports indicate that no fatal accident occurred in the slate industry in 1943 and that 175 men were injured by nonfatal accidents. Based upon these estimates the nonfatal-injury rate was 50.00 per million man-hours compared with a fatality rate of 0.45 and an injury rate of 74.44 in 1942, thus showing a material improvement in 1943.

TRAPROCK QUARRIES

Employment.—Reports indicate that 2,600 men worked 4.6 million man-hours in1943. This was a decrease in both the number of men working and the number of man-hours when compared with 1942. The number of employees was less by 17 percent than the number working in 1942, and the number of man-hours decreased 18 percent. Average working time was 208 days per employee, a loss of 4 days per employee.

Accidents.—Four men were killed and 280 suffered nonfatal injuries during the course of their employment in 1943. As a result, the fatality rate was 0.87 and the nonfatal-injury rate was 60.87, both being close to the rates shown by final reports for 1942, which revealed a fatality rate of 0.89 and an injury rate of 59.43.

GRANITE QUARRIES

Employment.—According to present reports, granite quarries employed 5,300 men in 1943, a decrease of 16 percent from 1942. The volume of employment was 1.3 million man-shifts or 11.0 million man-hours, the latter figure a decline of 12 percent compared with 1942.

Accidents.—Eight men were killed in 1943 compared with 14 in 1942. Nonfatal accidents decreased with man-hours of employment, but not in the same proportion. The number of nonfatal injuries is estimated at 480 compared with 531 in 1942. Accidents in 1943 resulted in a fatality rate tentatively placed at 0.73 and in a nonfatal-injury rate of 43.64. Similar rates for 1942 were 1.12 and 42.39, respectively.

SANDSTONE QUARRIES

Employment.—The number of men employed at sandstone quarries in 1943 maintained approximately the same level as that shown by final figures for 1942. A total of 2,,800 men worked 5.4 million man-hours during 1943; each employee averaged 231 days of work.

Accidents.—Estimates indicate that there were five fatalities in 1943 compared with one in 1942. Nonfatal lost-time injuries during 1943 resulted in disability to 348 employees. These accidents disclosed a fatality rate of 0.93 and a nonfatal-injury rate of 64.44, both rates being higher than those of 0.19 and 59.49, respectively, in 1942.

LIMESTONE QUARRIES

Employment.—Available reports indicate that 23,700 men were employed in the limestone-quarrying industry in 1943, a decline of 11 percent from 1942. The man-hours of employment decreased 6 percent, from 51.7 million in 1942 to 48.7 million in 1943. These figures do not cover limestone that was produced chiefly for the manufacture of cement or lime.

Accidents.—Accidents in and about the quarries and plants killed 31 men and injured 2,350. These accidents revealed a fatality rate of 0.64 and a nonfatal-injury rate of 48.25 compared with 0.58 and 48.98, respectively, in 1942.

LIMEKILNS AND ASSOCIATED QUARRIES

Employment.—Approximately 10,000 men were employed in 1943, a decrease of 6 percent from the number employed in 1942. Despite this decrease, the number of man-hours of employment was only slightly (2 percent) below the 1942 figure. Man-hours worked in 1943 are estimated at 25.2 million. The industry averaged 314 days of work per employee, indicating a gain of 8 days per man.

Accidents.—Fatal and nonfatal accidents increased in number in 1943. Incomplete reports indicate that 16 men were killed and 1,400 injured compared with 12 killed and 1,342 injured in 1942. The 1943 fatality rate was 0.63 and the nonfatal-injury rate 55.56 compared with 0.47 and 52.35, respectively, in 1942.

BYPRODUCT COKE OVENS

Employment.—Byproduct coking was one of the few branches of the mineral industries that reported increased employment in 1943. According to final and complete reports, the industry had 21,632 workers, an increase of more than 10 percent over 1942. Man-hours totaled 62.7 million, an increase of more than 10 percent. The operating time of the ovens was 363 days, indicating that nearly all active plants were operating full time throughout the year.

Accidents.—Fifteen men were killed by accidents, a record that compares unfavorably with that of 1942 when only 9 fatal accidents were reported. The number of nonfatal injuries increased from 545 in 1942 to 611 in 1943, causing the injury rate to rise from 9.60 in 1942 to 9.75 in 1943. The fatality rate for 1943 was 0.24 compared with 0.16 in 1942.

BEEHIVE COKE OVENS

Employment.—A decline in employment was reported for beehive coke ovens in 1943. Final figures are expected to show that 3,900 men worked during the year and performed 7.6 million man-hours of labor, a decrease of 11 percent in the number of employees and 10 percent in the number of man-hours worked. The operating time of the ovens averaged 274 days per employee, substantially the same as in 1942 when the average was 275 days.

Accidents.—Three men were killed and 340 men met with nonfatal lost-time injuries, according to present estimates. Thus the estimated fatality rate was 0.39 and the nonfatal-injury rate 44.74. These rates compare with the fatality rate of 0.47 and a nonfatal-injury rate of 44.49 in 1942.

ORE-DRESSING PLANTS

Classification.—The term "ore-dressing plant" or "mill" includes concentrators, stamp mills, sampling works, and slime plants; lixiviation, leaching, cyanide, flotation and tailing mills; crushing and screening plants; and sintering plants, calciners, washers, and driers. The men in this group were therefore engaged in the direct milling of copper, gold and silver, iron, lead, zinc, and miscellaneous metal ores.

Employment.—Ore-dressing and beneficiating plants or mills employed approximately 13,500 men in 1943, a small decrease from 1942. The plants as a group were in operation about 32.6 million man-hours, a decline compared with the 33.4 million worked in 1942.

Accidents.—Accidents to men employed at the mills killed 14 and injured 830 in 1943. These accidents resulted in a rate of 25.89 per million man-hours. The corresponding rate for 1942 was 27.24 per million man-hours and that for 1941 was 28.41, showing progress in accident prevention during the past 2 years.

SMELTERS

Employment.—The smelting industry, as used here, covers the smelting and refining of all primary metallic ores except iron ore. Employment and accident statistics covering iron-ore smelting and steel manufacturing are collected and compiled by the United States Department of Labor and hence are not included in Bureau of Mines figures. Reports for the smelting industry, as thus defined, show that 20,400 men were employed in 1943. This figure represents a small loss compared with the 20,636 men employed in 1942. The man-hours worked during 1943 totaled 56.9 million, a slight increase over the 56.6 million worked during 1942. The period of operation of the smelters, considering all as a single group, averaged 343 workdays per employee. This was 6 days less per man than in 1942. Although smelting is normally a full-time operation, the figures show that some plants were not active for a full year.

Accidents.—Accidents to men employed at smelters during 1943 killed 11 men and caused lost-time injuries to 1,770. The fatality rate was 0.19, and the injury rate was 31.11 per million man-hours of work done. Each of these figures represents an increase over the corresponding rate of the previous year, when the fatality rate was 0.12 and the injury rate 30.52.

AUXILIARY WORKS AT ORE-DRESSING PLANTS AND SMELTERS

Employment.—The term "auxiliary works" covers all operations at mills and smelters not directly connected with milling and smelting processes, such as machine, blacksmith and carpenter shops, yards, general construction, etc. About 17,000 men were employed in 1943, representing little change from the 16,825 men employed in 1942. The man-hours worked during 1943 showed an increase to 46.7 million compared with the figure of 45 million in 1942.

Accidents.—Men employed in auxiliary works suffered 5 fatal accidents and 1,174 nonfatal lost-time injuries in 1943. These accidents indicate an accident-frequency rate of 25.25 per million man-hours, an increase over the rate of 23.52 for 1942.

SUMMARY, 1933–43

Continuance of the decline in the number of employees in the mineral industries of the United States brought the number of workers not only below the level of 1942 but also lower than any other year except 1933, the low point of the past 11 years. A quite different situation, however, obtains regarding the number of man-hours of work performed during the 11-year period. In fact, the volume of work done, as measured by man-hours worked, was greater during 1943 than during any other year except 1942. It is possible that final reports, when received from all companies, may carry the total man-hours for 1943 slightly above the number reported for 1942, as the present estimate for 1943, based upon incomplete reports, is within 1 percent of the final figure for the previous year.

A few highlights of the 11-year record of the mineral industries of the United States may be recited to compare the record of 1943, as estimated from incomplete reports, with previous high points or low points of the period covered. The number of workers in 1943 was, as previously stated, smaller than in any other year except 1933, when the number was 678,000; the highest point was reached in 1937, when the number reached almost 860,000. Man-hours worked during 1943, only a fraction of 1 percent under the preceding year, topped all other years under discussion and were 56 percent more than the 985,000,000 hours worked in 1933. Man-days worked during 1943 exceeded 203 million, which was about 3 percent less than in 1942 but 65 percent more than the number worked during 1933, the low-point year. Fatalities from accidents during 1943 reached an estimated total of 1,813 and exceeded by 46 percent the number reported for 1933, which was 1,242; nevertheless, the fatality rate in 1943, which was 1.18 per million man-hours of employment, was more favorable than the rate of 1.26 for 1933 because of the greater proportionate increase in man-hours worked than in the number of fatal accidents. The 1943 rate, however, was not as favorable as that (1.12) for 1941, the year for which the lowest rate was reported. Nonfatal lost-time injuries, estimated at 90,927 from reports for 1943, were 27 percent above the 71,618 injuries that occurred in 1938 (the year of fewest injuries) and 26 percent above the 72,342 injuries reported for 1933 (the year ranking next to 1938 in the small number of injuries reported). However, the injury rate of 59.11 per million man-hours of employment for 1943 was more favorable than corresponding rates of 66.95 for 1938 and 73.48 for 1933, and the rate for 1943 was also more favorable than that of any other year of the period 1933–43.

Only an estimate can be made of the number of days lost as a result of accidents in the mineral industries during 1943, not only because many companies have not furnished their reports to the Bureau of Mines but primarily because the reports from the operators do not state the number of days lost from accidents at each mine. The number of fatalities and the number of nonfatal injuries are known, or rather these two facts will be known when all companies shall have reported; meanwhile, they can be estimated from reports already received. With this information, the lost time from both classes of accidents may be estimated. As each fatality is chargeable for statistical purposes with 6,000 lost days, the loss of 1,813 lives from accidents in the mineral industries during the past year may be said to represent the loss of 10,878,000 days. When final reports have been received covering nonfatal injuries (the number of which is at present estimated at 90,927) it will be found that some of the injuries caused the total, lifelong disability of the injured employees, other injuries will be found to have caused permanent but only partial disability, and still others will be found to have resulted in temporary disability. Permanent total disabilities, like fatalities, are chargeable with 6,000 days each; permanent partial disabilities vary in their time-loss charges according to the part of the body impaired and the degree of impairment; temporary disabilities are charged with the actual number of calendar days during which the injured employee, because of his injury, was unable to work. When all three classes of nonfatal injuries are combined, 85 days probably would represent a fair average of days lost per injury. Applying this average to the estimated 90,927 nonfatal injuries during 1943, the time lost as a result of the injuries was approximately 7,730,000 man-days. Thus the fatal injuries and the nonfatal injuries during 1943 represent a combined period of about 18,600,000 man-days. This disability chargeable to accidents was approximately 9 percent of the 203 million man-days worked by all employees in the mineral industries during 1943. In other words, as far as the time element is concerned, accidents were responsible for a 9-percent loss to the mineral industries during 1943.

This loss of manpower from industrial accidents during a global war is, to a great extent, an unnecessary addition to the unavoidable loss of life and limb in the military phases of the war. Military losses will stop when the war is won, but the losses from industrial accidents will continue during the post-war period. That accidents in the industry will continue to occur after military victory is achieved is a certainty. That the number of accidents in industry may be reduced is also a certainty; the only uncertain factor is the extent to which they may be reduced. The solution of the problem does not lie in the lap of the gods but rather in the lap of industry. Leaders of industry, or, more strictly speaking, a larger number of them, are the individuals on whose interest in accident prevention depends the saving of life and limb of miners and other industrial workers during the post-war years.

Marble industry, annual review........ 1288
Marble quarries, accidents........ 1597
  men employed........ 1591, 1597
Marvinol, uses........ 1530
Maryland, bituminous-coal industry, data.... 839, 842, 859, 860, 866, 870, 880, 881, 886, 889, 892, 895, 897, 903, 904, 907, 910, 926, 935.
  iron ore, data........ 591
  minerals, production........ 39, 44, 60
  potash, review........ 1503
  slate, data........ 1319, 1320
Masonry cements, salient statistics........ 1242, 1265
Massachusetts, granite, sales........ 1287
  minerals, production........ 39, 44, 61
McCarran bill, for disposal of silver from Treasury stocks........ 91
Medicinal oil, production........ 1161
Mercury, conservation order, relaxation.... 714, 715
  consumption........ 713, 714, 719, 720
  foreign trade........ 714, 726, 727
  prices........ 714, 718, 719
  production........ 713, 714, 715, 720, 721, 728, 729
  salient statistics........ 714
  stocks........ 720
  stock pile........ 713, 715
  supply........ 720
  uses........ 719, 720
Mercury compounds, foreign trade........ 727
Mercury industry, annual review........ 713
  post-war outlook........ 718
Mercury mines, producing, list........ 712
Mercury ore, deposits, Bureau of Mines and Geological Survey explorations........ 716
Mesothorium, foreign trade........ 825
Metal mines, miscellaneous, accidents........ 1596
  men employed........ 1591, 1596
  safety record........ 10
Metal mining, employment, highest priorities. 8
Metal-mining industry, minimum work week, establishment, by War Manpower Commission........ 9
Metals Reserve Co., contracts, cancellation, mercury........ 714
  vanadium ore........ 660, 665
  with China National Resources Commission, for mineral raw materials.... 26
  prices, graphite........ 1578
    manganese ore........ 620
    premium, lead........ 170
      zinc........ 188
  stock-pile purchases, arsenopyrite........ 754
    asbestos........ 1474
    bauxite........ 686
    bismuth........ 762
    chromite........ 626
    columbite........ 823
    copper........ 135
    lead........ 176
    manganese ore........ 607
    mercury........ 714, 715
    mica........ 1513
    molybdenum........ 653
    steatite........ 1432
    tantalite........ 823
    zinc........ 196
    zircon........ 831
  stock-piling, review........ 11
  tungsten-ore re-treatment plant........ 670, 672, 674, 675, 676, 677, 678
Mexican jade, hoax........ 1569
Mexico, antimony, data........ 786, 688, 790
  arsenic, data........ 756, 758, 759
  bismuth, data........ 763
  cadmium, data........ 795, 796
  copper, review........ 156, 158, 161, 165
  fluorspar, data........ 1460, 1461, 1462
  gold, production........ 90
  Government-to-Government agreement with, mineral raw materials........ 25
  iron ore, data........ 582, 584
  lead, review........ 180, 181, 184
  mercury, deposits, Geological Survey investigations........ 717
  molybdenum, data........ 657, 658, 659
